Notice is hereby given that a Meeting of Medical Men and Women under the Chairmanship of Sir LEONARD HILL, M.B., F.R.S., for the purpose of FORMING A SOCIETY OF PHYSIOTHERAPY will be held on Friday, November 14th. Those who desire to be present at this meeting are invited to apply for invitation to the Acting Hon. Sec. Dr. P. KYLE BROWN 17 Feather stone Bldgs., London, W.1.

It should be noted that Radiography and Radiology are not deemed to be branches of Physiotherapy.

APPOINTMENTS—Contd.

Staffordshire, Wolverhampton, & DUDLEY JOINT COMMITTEE FOR TUBERCULOSIS

TUBERCULOSIS OFFICER.

The Joint Committee invite applications for the post of *Tuberculosis Officer* for the Dudley and Wednesbury Dispensary Areas at a commencing salary of £750 per annum rising to £850 per annum together with travelling expenses.

Candidates should either have held a previous appointment as Tuberculosis Officer with the approval of the Ministry of Health or should since qualification

(1) have had at least three years experience in the practise of their profession,
(2) have spent in general clinical work a period of not less than eighteen months of which not less than six months have been spent in a hospital as resident officer in charge of beds occupied by general medical or surgical cases, and
(3) have received special training for a period of not less than six months in the diagnosis and treatment of tuberculosis.

The successful applicant will be required to act as Visiting Medical Officer of The Limes Sanatorium for Children, Himley, and will work under the administrative control of the Medical Officer of the Joint Committee.

Applications stating age, with copies of three recent testimonials, must be forwarded to the undersigned not later than November 6th.

County Buildings, Stafford. EUSTACE JOY, Clerk of the Joint Committee.

Hospital for Consumption and DISEASES OF THE CHEST, Brompton, S.W.3

The Committee of Management invite applications for the post of *whole-time qualified* ASSISTANT in the Department of Pathology. Duly qualified women are eligible for appointment. Further particulars may be obtained at the Hospital. Salary £350 per annum. Applications with copies of testimonials must reach the undersigned not later than Saturday, November 22nd. Candidates will be required to attend the Meeting of the Medical Committee on Wednesday, November 26th, at 4.30 p.m.

Brompton, S.W.3. FREDERICK WOOD, Secretary.
October 1930

The Mount Vernon Hospital, NORTHWOOD, MIDDLESEX (National Centre for the Study and Treatment of Cancer)

There is a vacancy for a RESIDENT MEDICAL OFFICER. Candidates must be fully qualified and registered. Salary at the rate of £300 per annum with board, lodging, etc.

Applications with copies of three recent testimonials to be sent to the undersigned not later than November 12th.

Offices, Fitzroy Square, W.1. W. J. MORTON, Secretary.

Redlands Hospital for Women, GLASGOW, W.2

Required Medical Woman for the post of HOUSE OBSTETRICIAN for six months. Salary at rate of £50 per annum. Applications with copies of three testimonials to be sent to JANET F. STEEL, Medical Secretary.

Warrington Infirmary and DISPENSARY

ANÆSTHETIST

The Board of Management invite applications for the above post.

Attendance at the Hospital is required on six days per week in the mornings up to noon.

The Board are prepared to form a rota of two or three Medical Practitioners if it is impossible for them to secure a candidate for the full six days.

An honorarium of £150 will be paid or if the rota is made this sum will be proportionately divided.

As this is a part time post the position may appeal to those Practitioners who are holding other part time posts or studying for higher degrees.

Applications should be sent in to the undersigned at once stating qualifications and also the number of days they wish to attend.

By Order,
HENRY L. BOOT,
October 28th 1930. Supt. & Secretary.

HORMOTONE
BRAND

in disorders of the

CATAMENIA

and the

MENOPAUSE

Hormotone supplies the physiological stimulus to the endocrine glands, whose functional activity determines the normal catamenial flow

When these internal secretions begin to fail at the period of the menopause, Hormotone acts both by substitution and homostimulation

Dose One or two tablets three times daily

G. W. CARNRICK CO.

BILIARY STASIS AND GALL-BLADDER DISEASE

It is stated that ten per cent of our entire adult population suffer from gall-stones As gall-stones presumably always follow infective inflammations of the gall-bladder must be even more common

The relative frequency with which the gall bladder is infected on the one hand by the bile received from a liver whose detoxicating capacity has been lowered and on the other hand directly by the blood supplied through the cystic artery is not determined but in either case biliary stasis is a prominent aetiological factor in actual gall bladder disease The importance of promoting more active intestinal peristalsis and a hastened biliary flow is therefore obvious Through the force of gravity the flow of bile into the intestine may as the duodenal tube has revealed be stimulated by suitable saline draughts of which Eno's Fruit Salt is perhaps the most agreeable and most generally useful It is suggested that many early cases of cholecystitis —apt to be cursorily dismissed with the vague diagnosis dyspepsia —might be arrested by such simple means as increased exercise and a regular morning draught of Eno's Fruit Salt

Eno's chemically pure and free from all trace of the nauseous mineral sulphates —Glauber and Epsom It contains no sugar or artificial flavouring

The Doctor's Pocket Reminder

The Proprietor of ENO's Fruit Salt will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders —with or without a bottle of their preparation as desired The Doctor's Emergency Reminder summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases It is bound in black morocco limp to conform to the style of previous publications in this series

J C Eno Ltd 10 Bunhill Row London E C 1

ENO'S "FRUIT SALT"

Measuring Progress by the Therapeutic Yardstick

ANCIENT medicine set great store by "specifics" Paracelsus had his "Specificum Purgans" Cophon relied on mirobolanum or rhubarb in relieving constipation Suppositories of honey and oxgall had their day in the fifteenth century

Medicine has since made notable advances toward rationalism In this day of therapeutic progress Agarol Brand Compound holds the foremost place An exceptionally fine emulsion of mineral oil and agar-agar with phenolphthalein, it is not merely a laxative, but a remedial measure in the efficient treatment of constipation

By introducing unabsorbable moisture, Agarol Brand Compound keeps the intestinal contents soft and makes their passage easy and painless By *gentle stimulation* of peristalsis, it makes the result certain and aids in re-establishing normal bowel function

One tablespoonful at bedtime —is the adult dose

Final decision on the true worth of Agarol Brand Compound rests with the physician We will gladly send a liberal quantity with literature, for trial

AGAROL BRAND COMPOUND *for Constipation*

FRANCIS NEWBERY & SONS, LTD, 31-33, Banner Street, London, E C 1.

DIAGNOSIS OF MENTAL DEFICIENCY

By HENRY HERD, M A M B Ch B,

Senior Assistant School Medical Inspector City of Manchester Education Committee
Certifying Medical Officer to the Lancashire Mental Deficiency Authority

284 pp Demy 8vo Fully illustrated with 39 Half-tone and 11 Line Blocks

Published at **12/6** net, postage 6d

Dr Herd's book appears exactly when the questions raised by the recent Report of the Mental Deficiency Committee call for consideration from the medical profession and the public alike. The book provides for the medical practitioner the means to diagnose the presence of *mental deficiency* and indicates the real significance of moral defect. For the instruction of the psychologist it sets out in orderly form the tests of intelligence and temperament, explaining by illustrative cases how mental deficiency can be graded for the special information of the public the statutory duties imposed and the *powers conferred* by recent Acts of Parliament are included A valuable arrangement of material puts in the front an essay on the psychology of the normal subject, it being recognised that the greatest difficulties in social life arise in so-called border-cases, where the amount of lapse into abnormality has to be evaluated

The book will prove useful to the whole medical profession first to those whose duty it may be on any day to give counsel to the heads of families, and secondly to those whose routine business it is to issue official certificates Further by its pages school teachers will be helped to understand the difficulties of backward pupils, and all social workers will find much assistance in their work by consulting the section on general psychology and the discussion of moral cases

SYNOPSIS OF MEDICINE

By H LETHEBY TIDY, M A, M D, B Ch.Oxon, F R C.P Lond

Physician St Thomas's Hospital Consulting Physician Fyfield Victoria Hospital

An admirable *index medicus*. The subject matter than in the majority of books. The up-to-date treatment, combined with ample consideration this fact alone will enhance its value enormously for the busy practitioner.—*Dental Journal.*
We can say without hesitation that the book is far ahead of any medical synopsis it has been our lot to encounter.—*Lancet.*
We have nothing but admiration for this book, and cannot commend it too highly.—*Medical Press and Circular.*

There is no logical reason why any medical man should not have the advantage of X ray diagnosis always at his elbow

The inestimable value of X rays is universally appreciated. In the design of the "Metalix Portable" every possible objection to their use in general practice has been overcome Designed with a full appreciation of all the difficulties, the "Metalix Portable" is simple, safe, reliable and surprisingly compact. It can be operated anywhere—in the surgery at the patient's home, or even at the place of accident.

A 36-page brochure profusely illustrated, and explaining the "Metalix Portable" in detail will be sent on receipt of a post-card.

The illustration shows the "Metalix Portable packed. Everything is included in the suit case except the transformer (seen on the left)

LIVER EXTRACT B.D.H.

Literature on request

Reports upon the results of liver therapy in the various anaemias stress one point repeatedly—namely, the importance of the potency of the liver preparation for the achievement of success *(Lancet,* Sept 13th, 1930, p 582)

Liver Extract B D H is made by a process tested and found efficient by the Medical Research Council, hence, to ensure that a product of definite potency is supplied to his patient, the physician has merely to write his prescription thus—

℞ *Liver Extract B.D.H.*

Liver Extract B D H is issued in the form of a palatable powder convenient for administration

THE BRITISH DRUG HOUSES LTD. LONDON N-1

A NERVE FOOD OF ASCERTAINED VALUE

It is a demonstrable fact that every organ maintains its form and activity by means of a hormone which it produces A deficiency of this hormone is a frequent primary cause of disease

Medical research has shown that the nerve and brain cells depend to a great extent on the Lipoids and the chief value of New Promonta in the treatment of nervous ailments is in its retention, in an absolutely unchanged form and unvarying quantity, of the Lipoids, Phosphatides, Cholesterols, and Vitamins found in living and properly functioning nerve cells New Promonta has therefore a specificity of character which is of material aid in stimulating proper cell metabolism, in restoring cell wastage, and promoting a normal mental, nervous and bodily well being New Promonta is used in hospitals and clinics, and is prescribed by doctors throughout the country It will also be found of value in counteracting general debility and during convalescence

A physician's sample will be sent on request.

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

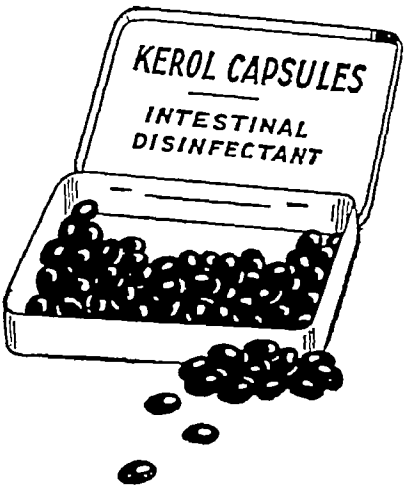
On receipt of your professional card a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap
Wright's Coal Tar Ointment
Wright's Lysol
Wright's Liquor Carbonis Detergens

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring, whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery

WRIGHT, LAYMAN & UMNEY LTD, 66, Park Street, Southwark, S E 1

ALIMENTARY TOXAEMIAS



IN our last advertisement the subject of Alimentary Toxæmia was briefly discussed, and intestinal disinfection by means of Kerol Capsules was held to be the first line of treatment

The reason for this may be stated as follows —None of the ordinary so-called intestinal antiseptics, such as Salol and Beta Naphthol, are found experimentally to exert any disinfection of the contents of the bowel

On the other hand, the high boiling hydroxyl compounds of the coal tar series are potent germicides, and, being unabsorbed, are non toxic. They can therefore be administered freely without harm, and are found to prevent the multiplication of the toxæmic intestinal bacteria and to reduce them considerably

The active principle of Kerol is a complex mixture of these compounds The administration of two 3-minim capsules thrice daily after meals has been repeatedly shown to reduce the coli content of the stools of individuals taking them by 99 per cent

For intestinal disinfection, use KEROL CAPSULES (keratin-coated), they contain 3 minims of Kerol One to three capsules may be given three or four times a day after meals

Kerol Capsules

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate
May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced
It cannot harm the most delicate constitution and is at all times a safe and effective laxative
Manufactured in London for the past 100 years.

MEDULLA RUBRA

BONE-MARROW IN ANAEMIA FROM HAEMORRHAGE

W Borchardt (*Deut med Woch* March 28th 1930 p 521) records the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood In the first series some of the animals were fed with rib marrow, others with marrow from the long bones Control animals received a corresponding amount either of fat or of liver extract The basal diet in each case contained a sufficiency of iron (5 mg per cent) Only the animals receiving the red rib marrow showed a definite increase of weight and their haemoglobin formation was more rapid than that of the others In the next series the experiment was repeated, but the iron content of the diet was reduced to 1 4 mg per cent The result was similar but more striking the dogs receiving the rib-marrow regaining their haemoglobin far more quickly than the others

THIS extract from the "Epitome of Literature," published in the "BRITISH MEDICAL JOURNAL," dated May 3rd last, is important as representing, in 1930, a complete justification of the formula upon which

Roboleine

THE FOOD THAT BUILDS THE BODY

has been produced without variation during the past twenty-five years

The success of ROBOLEINE is thus due to intelligent anticipation and to consistently maintaining the highest possible standard of manufacture

Medical Practitioners are asked to satisfy themselves of the merits of ROBOLEINE, for which purpose testing samples will be gladly sent upon request.

Balanced Vitamin feeding essential to Health

DISAPPOINTMENTS arising from a too ready acceptance of the exaggerated claims made for certain vitamin treatments should not be allowed to obscure the important part that vitamins fulfil in a properly balanced diet.

Such disappointments are due to a false conception of the function of vitamins as a cure for all human ills, whereas what has been definitely ascertained is that the vitamins are one of several important factors in a diet, which if it is to fulfil all the requirements of health must be of correct physiological balance and suited to the powers of assimilation.

The influence of Virol on health and development is due to the manner in which the vitamin foods together with the all important mineral salts, are in properly balanced proportions to the needs of perfect bodily health and to the remarkable ease with which Virol is assimilated. There is no other food that contains all the ingredients of Virol in the same scientifically balanced proportions

VIROL LIMITED EALING LONDON W.5

For Building up Resistance

The problem of dealing with patients who are especially liable to attacks of every prevailing infection is one that frequently faces the practising physician In such cases of subnormal health and lowered resistance a scientifically-standardised product of the nature of Radio-Malt is of particular value at this season

Radio-Malt is a potent anti-infective agent, and its routine administration during the autumn safeguards against infection during the winter

RADIO-MALT

Vitamins A B_1 B_2 and D

Physician's sample for clinical trial on request

THE BRITISH DRUG HOUSES LTD LONDON N-1

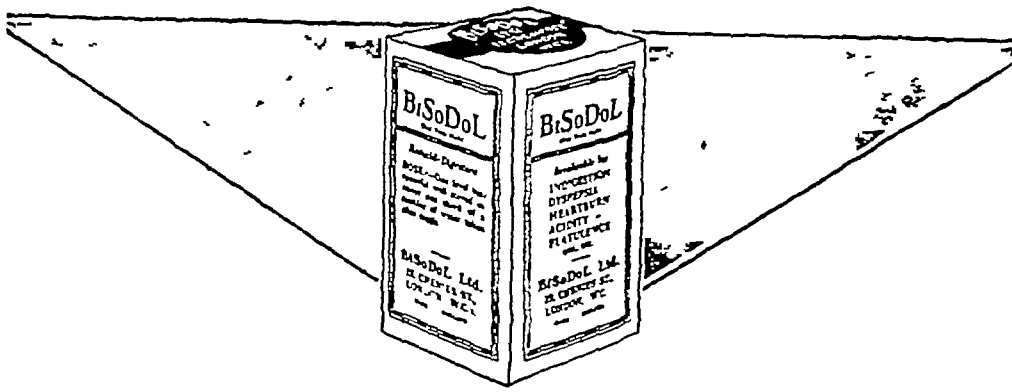
VP 197

The "Common Cold" and Nasal Catarrh.

In the fluctuating temperature of the English winter disinfection of the naso-pharynx is regularly required to avoid the insidious settlement and development of infecting germs on

Mucous Membranes of Weakened Resistance

A preparation which can prevent infection of such an important area should appeal to every practising physician—and such a preparation is available in



DIMOL SNUFF

whose high bactericidal potency and freedom from deleterious action make it an ideal preventive

Children can be easily taught to take it in small pinches.

Prices and particulars will be sent on application to

DIMOL LABORATORIES, LTD, 40, LUDGATE HILL, LONDON, E C 4

An Effective Antacid and Digestant

The Physician is constantly called upon to prescribe for digestive disturbances In the treatment of such cases, BiSoDoL will be found a reliable preparation

BiSoDoL is a balanced formula presenting in suitable proportions the bases Sodium and Magnesium, with Bismuth Subnitrate, Carica Papaya, Malt Diastase and Mentha Piperita

BiSoDoL is agreeable to the Patient and no unpleasant symptoms follow its administration

BiSoDoL is quickly effective. Beneficial results have been especially marked in cases of impaired digestion, and in the control of cyclic vomiting, and the morning sickness of pregnancy

BiSoDoL

Samples will be gladly sent to Physicians on request.

BiSoDoL Limited,
12, Chenies Street, London, W.C. 1.

SEASONABLE PREPARATIONS

ELIXIR
RIBES NIG. CO.
(DUNCAN)
A combination of Codeina Ipecac, Menthol, etc, flavoured with Syrup Ribes Nig, which is prepared from the finest fresh fruit

Duncan

ELIXIR
TERPO-CODEIN. CO.
(DUNCAN)
A pleasantly flavoured elixir, containing Codeina Phosphate and Terpin Hydrate in a suitable basis

THESE ELIXIRS ARE MOST SUITABLE FOR THE TREATMENT OF COUGHS IN CASES OF PHTHISIS, CHRONIC BRONCHITIS, CATARRH, ETC

SAMPLES AND PRICES ON APPLICATION

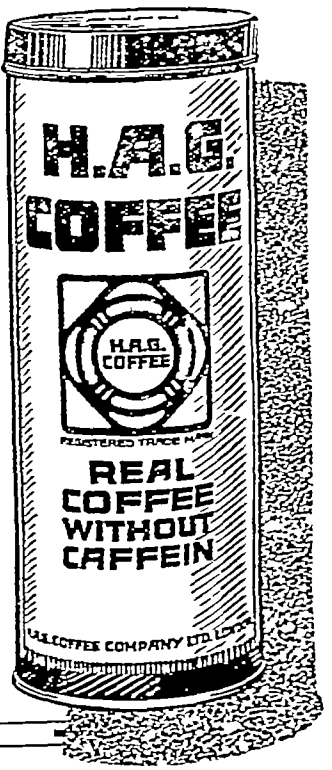
For neural patients

DELICIOUS H.A.G. COFFEE — 97% DECAFFEINIZED



CAFFEIN is never prescribed for neurasthenia, hysterical, insomnious or psychopathic patients It is too well known how this drug shortens reaction time, excites the reflex arch of the spinal cord, and stimulates the nervous system generally, as shown on the chart at the right.

This is why coffee is forbidden is such cases But it is not necessary to make this usually vain attempt to change the habits of coffee drinkers Instead of saying "Stop coffee simply say "Drink H A G Coffee H.A G Coffee causes practically no increase in nervous stimulation, as the illustration above indicates

Sold in 1/6 tins packed under vacuum

Special 5 lb tin for Medical Profession 13/6

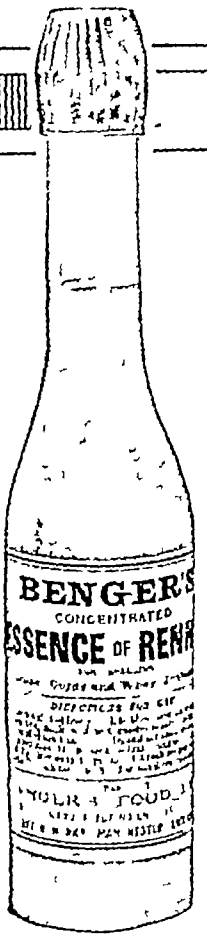
NOT A SUBSTITUTE

H.A.G COFFEE, although 97% decaffeinized is not a substitute It is blend of the choicest Central American and South American coffee berries, combined in just the right proportion to give that tasty fragrance and flavour found only in coffees of the highest grade Its taste is not impaired in the slightest because the caffein is extracted from the raw beans—before they are roasted

H.A G Coffee is the same coffee as the coffee known on the Continent as Kaffee HAG and in America as 'SANKA COFFEE. It is very highly recommended by the Medical Profession abroad and practically no other coffee is consumed in such health resorts as Bad Nauheim, Carlsbad, etc., etc.

A TRIAL TIN WILL ALSO CONVINCE YOU

Obtain a liberal sample by sending in the attached coupon to-day



H A G COFFEE COMPANY Ltd
40 Theobald's Road London W C 1

Please send me free of charge a liberal sample of H A G Coffee—also the booklet Some Observations of the Action of Caffeine.

ESSENCE of RENNET

CONCENTRATED (BENGER).

(Curdling Fluid)

Originally prepared at the request of a prominent physician, this highly concentrated essence is of especial value in Infant and Invalid Feeding As it is concentrated it is much quicker in its effect than most other preparations of Rennet Whey prepared with Benger s Essence of Rennet is of the greatest value in the treatment of diarrhœa, vomiting, etc , it can be employed with confidence and will yield good results Junket can be made more quickly and at a lower cost by using Benger's Essence of Rennet than by any other method.

In 1/- and 1/9 bottles

Larger sizes for hospitals, etc , use.

LIQUOR PEPTICUS

(BENGER)

"A digestive agent of extraordinary power."

Sir William Roberts, M D , F R S

Benger's Liquor Pepticus, is a concentrated and highly active fluid pepsin in acid solution which acts particularly upon meat, eggs and other proteid foods

The best results from the use of Liquor Pepticus are obtained when it is prescribed alone Should the prescriber wish to combine medicaments of a tonic nature, it will be recollected that those which are free from astringency and alkalinity should be selected

In 4, 8 and 16-oz. bottles

Prices: 3/6, 6/6 and 12/6

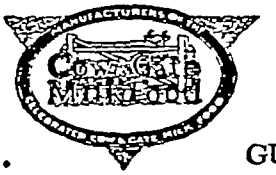
BENGER'S Food

NATURALLY RICH

IN VITAMIN "D"

A RELIABLE BASIS

THE above chart shows the large fluctuations in the fat content of liquid milks throughout the year, as compared with the unvarying fat content of "Cow & Gate," which is based on the fat content of average healthy Breast Milk.



Fat content in "Cow & Gate" reconstituted (1 in 8), 3.4 per cent.

Fat content in average Breast Milk 3.3 per cent. to 3.5 per cent.

The fat content of raw milk also varies greatly from day to day. The time of day at which milking takes place also causes considerable variations.

This is in striking contradistinction to the standardized fat content of "Cow & Gate" and affords one of the many reasons why this food is the safest and most reliable alternative when breast feeding fails, and why it affords the most reliable basis for Infant Feeding Modifications.

Write for literature and clinical samples of Lacidac and Brestol

Support HOME Agriculture. Cow & Gate Products are all made from ENGLISH MILK

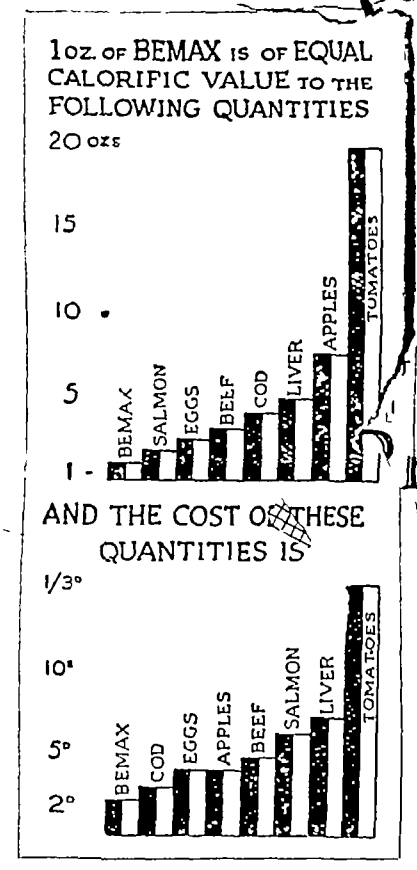
COW & GATE LTD. GUILDFORD, SURREY ©

What is "BEMAX"?

"BEMAX" is a natural vitamin tonic food prepared under the direct supervision of members of the medical profession, from the embryo or germ of cereals specially selected for their vitamin content—such cereals as wheat, rye, or barley

It has sometimes been stated that "BEMAX" consists chiefly of bran This emphatically is not so, since every possible precaution is taken to eliminate bran completely from "BEMAX" The cellulose content is kept down to approximately 1%

The analysis of "BEMAX":



Protein - -	37.2%
Fat - - -	9.0 "
Ash - - -	4.51 "
Moisture - -	6.0 "
Fibre - - -	1.5 "
Carbohydrate -	41.79 "

It will be noted that the carbohydrate content of "BEMAX" is slightly more than 41%, and it has often been asked if, because of this, "BEMAX" could be given to diabetics Since only one tablespoonful of "BEMAX" is taken daily the carbohydrate intake is so small that "BEMAX" can confidently be given in such cases

The Ash on analysis gave the following

CaO - - - -	0.12%
MgO - - - -	0.65 "
P_2O_5 - - - -	2.70 "
K_2O, Na_2O - -	1.04 "
Fe_2O_3 - -	Trace
Total Ash -	4.51 "

An interesting feature of this analysis is the high percentage of P_2O_5, which undoubtedly accounts for the fact that in experiments on rickets we could not produce rickets in animals fed on a rickets-producing diet plus "BEMAX"

The food value of "BEMAX" is probably best demonstrated by comparing its calorific value with that of other foods.

The upper chart shows the amount of different foodstuffs required to give the same calorific value as 1 oz of "BEMAX" and comparative costs are shown in lower chart. It will be noted that "BEMAX" is one of the cheapest foods.

In spite of the fact that the protein in "BEMAX" is vegetable protein, prolonged tests on birds proved that this protein is equal in every way to that of meat or fish This property makes "BEMAX" a suitable addition to the food of those subject to great strain or arduous work.

In our opinion, however, the most important result of these experiments is that when "BEMAX" is added to the diet more nourishment is absorbed from other foods than when "BEMAX" is not included.

We maintain that "BEMAX" has a greater proportion of vitamins B_1, B_2, B_3 than has any other product of its kind

Next in importance is the E vitamin We believe that no other food is as rich as "BEMAX" in this important vitamin "BEMAX" also contains vitamin A

Detailed reports of further research work will be sent on request

BEMAX

Max-imum Natural Vitamin B.

Samples of Bemax for personal test and full reports of the laboratory experiments outlined above will be sent on application to any Medical Practitioner on request to

THE BEMAX LABORATORIES,
38, DANEMERE STREET, LONDON, S.W.15.

HEWLETT'S
ORIGINAL PREPARATIONS.

HORMONIGEN
(HEWLETT'S)

Hormonigen Tablets (Hewlett's) contain the hormones of the thyroid pituitary ovary and testes

Useful in Neurasthenia and all asthenic conditions obesity chronic cardiac cases aplasias of the pluriglandular system and in anæmia In Amenorrhœa Dysmenorrhœa and at the Menopause Hormonigen is particularly effective and even in chlorosis

If there is high blood pressure Hormonigen Sine Pituitary is indicated

UNG. IODERMIOL

An ointment of IODERMIOL that contains about 5 per cent of Iodine and is therefore stronger than the B P Ointment whilst it does not harden or discolour the skin

It has been found most useful for Enlarged Glands Rheumatic and Gouty Affections Lumbago Sciatica Swollen and Stiff Joints Skin Diseases Ringworm etc Ung Iodermiol has also been used in cases of burns and scalds and in the treatment of Chronic Lymphadenitis Simple Bronchocele and Atrophic Rhinitis, and in Purulent Ulcerative Otitis

PRICE 6/- PER LB

UNGUENTUM IODERMIOL et METHYL SALICYL (HEWLETT'S)

Useful in the treatment of Enlarged Joints, Synovitis Rheumatoid Affections etc.

PRICE 7/6 PER LB

LIN. BETULAE CO.
(HEWLETT'S)

Therapeutically equivalent to several times its weight of Sodium Salicylate without causing headache, tinnitus, etc Has proved most useful in the external treatment of pure Rheumatism, Sciatica, Lumbago, etc The external dose is about one drachm rubbed over the affected parts

In 5, 10, 22, 40, and 90-oz Bottles

PRICE 10/6 PER LB

VERONIGEN
(Formerly known as MIST VERONAL CO.)
(HEWLETT'S)

A liquid Preparation of this prompt and reliable HYPNOTIC has long been desired as a useful means of procuring sleep When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever and in ordinary cases of insomnia one fluid drachm of Veronigen (Hewlett's) is quite sufficient dose for an adult.

Dose for Adults.—One fluid drachm diluted about one hour before going to bed

For Nervous Sleeplessness in Children.—10 to 20 minims diluted

VERONIGEN, 10/6 PER LB

MIST. PRUNI VIRG. CONC.
(HEWLETT'S)

A valuable stimulant and expectorant cough mixture, containing Carbonate of Ammonium, Ipecacuanha, Senega, Squill, and Syrup of Wild Cherry Bark Quite free from Morphine, Opium, or poisons, so can be safely administered to children

Dose 1 to 2 drachms diluted

In 22, 40, and 90-oz Bottles only

PRICE 3/3 PER LB

MIST. TUSSI RUB. CONC.
(HEWLETT'S)

A favourite and economical cough mixture, containing Hydrobromic Acid, Chlorodyne, Dilute Hydrocyanic Acid, etc Most successful in allaying post-influenza coughs that are so persistent One or two ounces diluted with water to make eight ounces forms one of the most effective and elegant mixtures that can be made, and certainly the least expensive

In 22-oz, 40-oz, 4½-lb, and 8-lb Bottles only

PRICE 2/9 PER LB

COLLUMINA

A colloidal aluminium hydroxide

The therapeutic value of Collumina depends upon its ability to absorb the excess acidity of the stomach without giving rise to the unpleasant secondary reactions which often follow the administration of alkalies

In addition, Collumina acts as a deodorant and is very effective in overcoming fetor of the breath

Being mildly astringent and non-toxic, it is recommended as a mouth wash or gargle for the relief of congestion of the mucous lining of the mouth and pharynx

Collumina is pleasantly flavoured and is supplied "plain" and also combined with phenol-phthalein for cases of intestinal stasis, and with bismuth for intestinal colic and diarrhoea

Issued in 4-oz, 8-oz, and 16 oz bottles

Prepared at
Evans' Biological Institute,
Higher Runcorn, Cheshire

ALOCOL

Colloidal Hydroxide of Aluminium

For Chronic Irritations of the Gastric Mucosa

WHEN alkaline therapy is indicated "Alocol" is the preferred form of treatment Its advantages over the usual oxides and alkalis are manifest Whilst the preparations in common use give momentary relief to painful symptoms they aggravate the morbid condition Consequently such remedies are contraindicated, especially in stubborn, chronic cases

The action of "Alocol" is superior in every way, because it does not merely confine itself to combating the symptoms of the trouble, but attacks the origin itself

"Alocol" fixes the acid, not by neutralization, but by adsorption It relieves pain, is slightly astringent, and limits the acid secretions "Alocol" is always well borne, no harmful secondary action follows its administration, and its therapeutic effect is not diminished with prolonged use

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request

A WANDER, Ltd, Manufacturing Chemists,

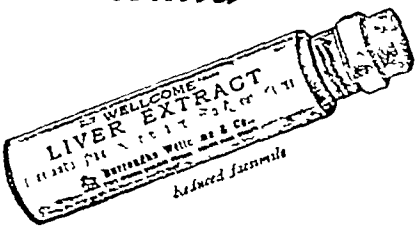
Works KING'S LANGLEY, HERTFORDSHIRE

M 230

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced

"Alasil" completely overcomes this objection By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract "Alasil" is therefore a triumph over acetyl-salicylic acid It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time Analgesic, Antipyretic and Sedative, "Alasil" is indicated in all cases where acetyl salicylic acid has been used heretofore



A supply for clinical trial with full descriptive literature sent free on request

Remarks on THE MEDICAL ASPECTS OF THORACIC SURGERY *

BY

R. A. YOUNG, C.B.E., M.D., F.R.C.P.

SENIOR PHYSICIAN TO THE MIDDLESEX HOSPITAL; PHYSICIAN TO THE BROMPTON HOSPITAL, LONDON

Thoracic surgery at the present time is a medical subject of absorbing interest. Although drainage of empyema is perhaps one of the earliest of surgical procedures, and although a few pioneer efforts, both experimental in animals and clinical in man, served to point the way, the real advance in thoracic surgery have occurred in the period of a generation—in fact within this century. They have not however been slow in developing. Thoracic surgery has emerged from the tentative, experimental, and groping stage into one of well-established technique and of great achievement. Surgeons, physicians, radiologists, and anæsthetists may well be proud of the advances which their co-operation has achieved. It needs no great gifts of prophecy to foresee even greater triumphs in the future.

Application of Surgery to Thoracic Disease

The physician appeals to the surgeon for assistance when his own efforts have failed or when he is almost helpless *often owing to the difficulties* of access to the affected structure or organ. Medical failures are too often tragedies leaving *the patient maimed, suffering* and uneconomic. In no special department is this more true than in thoracic disease. The intrathoracic organs are literally of such vital importance that their disease or damage often results in severe and even dangerous consequences. Fortunately, as Meltzer pointed out, nature is generally lavish in providing "spares" or at any rate compensatory mechanisms.

It is perhaps not yet recognized as widely as it should be by practitioners or by patients, at least in Great Britain, how much help surgery can give in some of these grave intrathoracic conditions where medicine is impotent or confined to palliation. Thoracic surgery is now capable of yielding, and is *indeed daily giving results* without prohibitive risk comparable in their usefulness with those of abdominal surgery.

Consider a case of chronic pulmonary abscess failing to drain effectively into a bronchus, accompanied by copious offensive sputum and slowly progressing to incurable bronchiectasis, making the patient a misery to himself and a continual source of distress to his relatives. He who has seen such a patient restored to sound, robust health, and full working capacity will surely approve, admire, and recommend this beneficent application of surgery.

A successful thoracoplasty in a case of pulmonary tuberculosis is another medico-surgical triumph which cannot fail to impress. To restore a patient suffering from chronic and progressive ill-health, and faced with the prospect of diminishing comfort and ever increasing limitation to active and even full economic life, is a gratifying achievement which is daily becoming more common.

Such instances can be multiplied many times. They serve to emphasize the importance of a discussion of this kind, for the benefits of surgery should not now be withheld from suitable cases on the grounds that the procedures are experimental or associated with undue risk. They are now well established, and have universal or international sanction and approval, and a statistical warranty calculated to give confidence.

The medical aspects of this important development of the surgical art are very wide and are difficult to define and to delimit. They involve:

1. The diagnosis of the condition requiring operation.
2. The assessment of the patient's suitability for operation, notably his capacity to bear successfully all that it may involve.
3. The choice of surgeon.
4. *The discussion* of the operative measures proposed and their adaptation to the condition present—for example, the question of operation in stages.
5. The preparation for operation and the after-care of the patient, both immediate and remote.
6. The decision as to the time for surgery.

Diagnosis of Condition

The diagnosis of intrathoracic disease, especially of morbid condition at the bases of the lungs or of the mediastinum, may be a matter of great difficulty. Fortunately these conditions rarely involve emergency operation. There is usually time for full investigation, and the experienced thoracic surgeon naturally demands that this should be done. Careful consideration of the history, symptoms, physical signs, and course of the patient's condition may suggest a diagnosis but, where practicable, every investigation likely to help in establishing its accuracy should be undertaken.

The improvements in radiological technique have contributed in very large measure to the advances in the diagnosis and surgical treatment of intrathoracic disease. Complete radioscopic and radiographic investigations including lateral and oblique views are now essential in almost every case. The lateral and oblique radiograms, especially the former, may give crucial information. Investigation of the bronchial tree by means of lipiodol in suitable cases may determine the diagnosis and give extremely valuable information in regard to the suitability for operation. Bacteriological, haematological, and other *clinical laboratory methods may contribute to the solution* of the problem of diagnosis. Even exploratory procedures varying from the puncture to artificial pneumothorax and exploratory thoracotomy may be necessary. As a physician I should like to deprecate exploratory puncture at random, where intrapulmonary suppuration is suspected. It may be the cause of disaster if the pleura in the region of the puncture is not adherent. In case of any exploratory puncture or thoracotomy the surgeon should if possible have permission to proceed to full operative treatment and be prepared to do so. Bronchoscopy comes into the same category, *since it may not only establish the diagnosis* but may be the means of operative cure.

Assessment of the Patient's Suitability and Capacity

This is a much more difficult matter and depends upon less ponderable factors. Urologists have set physicians an excellent example and a high standard of attainment in their methods of investigation of renal function before operation. I think that there is scope for research in the measurement of respiratory efficiency. The estimation of 'vital capacity' may be helpful. The normal is enormously greater than is necessary for the bare maintenance of life, the *minimum being in effect the* tidal air which is obviously enough to provide adequate respiratory exchange at rest, provided that there is sufficient lung area undamaged for aeration purposes. A very low vital capacity may be a bar to operation. At present we have to rely more upon a careful clinical review of the patient's general condition, taking into consideration factors like age, physique, temperament, blood pressure, and the general nutrition. The sedimentation rate of the erythrocytes may prove to be of some value in this connexion, but at present its significance is debatable. The ultimate decision rests rather upon "clinical instinct"—that is an almost intuitive assessment of the patient's condition and capabilities. Personally I now find myself advising surgical intervention in cases where a short time ago I should have hesitated. None the less some more explicit criteria are desirable.

Choice of Surgeon

A great responsibility rests upon the physician or practitioner in choosing a surgeon. The more difficult operations in this field of surgery should be entrusted in my opinion to those with special experience. Time in operations involving extensive rib removal may be of vital importance. A few minutes may make the difference between success and failure. Moreover there is more than

* Made to a joint meeting of the Section of Surgery and Tuberculosis at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

operative technique to be considered There is the necessity for great judgement in deciding what should be done and how much should be attempted Thoracic conditions often require several operations or several stages in one operative scheme Fortunately, there are now teaching centres in almost, if not all, English-speaking countries where thoracic surgery of the best type can be studied and where experience can be gained

The physician recommending surgery is well advised to observe the surgeon at work in order to learn what the procedure he advises may entail It is also desirable—indeed necessary—that the surgeon should have a good and practical knowledge of the medical aspects of thoracic disease, including the significance of physical signs I am bound to say that every thoracic surgeon I have known has amply fulfilled this condition It is always stimulating and instructive to discuss cases with them, since they have the experience of what has been so aptly called "the pathology of the living"

This question raises an interesting speculation whether this branch of medical work is likely to develop a type of specialist worker who will deal with thoracic disease from all aspects—that is, both diagnostic and therapeutic—by regimen, medicine, or operation Some of the pioneers in this field have conformed to these conditions, like Brauer, Sauerman, Graysesen, and Morriston Davies, and their names stand high in the roll of achievement It is probable that the developments will vary in different countries In England, at any rate at the present time, properly organized and co-ordinated team work seems likely to give the best results

Discussion of Measures Proposed

The physician discusses with the surgeon the morbid conditions and the measures most likely to yield good and permanent results Although the surgeon from his experience is the best judge of what he is likely to achieve, yet the physician knows what he desires to attain, and free and friendly discussion and criticism have in my experience been very helpful The physician has to bear the responsibility of advising operation, and he should take his share in deciding what is to be done At the same time it is obvious that the ultimate decisions may be influenced by what is found at the operation, and the surgeon should have a free hand to proceed as may seem best

Preparation for Operation and After-care

It is important to recognize that in thoracic surgery the patient should be in the optimum condition Some days occupied in preparation may be time well spent, and practitioners should recognize this and warn patients and their friends when advising recourse to surgery Similarly, skilled after-care and nursing are of the utmost importance, and may contribute not only to the comfort of the patient but also to the success of the result, particularly in conditions like thoracoplasty, abscess, and empyema These are matters of which the physician and the practitioner should have knowledge, though the responsibility is the surgeon's Strict attention to details may be of the utmost importance to the patient

Time for Surgical Intervention

Emergency operations are few, and are confined practically to

(*a*) Relief of positive pressure in valvular pneumothorax

(*b*) Immediate artificial pneumothorax in cases of severe or recurrent haemoptysis

(*c*) Partial aspiration of a large effusion causing oedema of the opposite lung or dangerous mediastinal displacement, impeding its respiratory activity

(*d*) Aspiration of empyema in a seriously ill patient, as a preliminary to effective drainage

( ) Tracheotomy in bilateral abductor paralysis from pressure on both recurrent laryngeal nerves

On this occasion I can only refer briefly to the time when the surgeon should be invited to help in medical diseases of the thoracic organs In regard to pulmonary tuberculosis, artificial pneumothorax has established itself as a therapeutic method of the highest importance, and the indications are well recognized Where this fails, or is impracticable, the question of the cause of failure has to be considered—local adhesion, large apical cavities, or general adhesion

I have an open mind on the subject of cutting adhesions, I hope that the more recent methods may render this procedure of greater usefulness Except in very small and localized adhesions I am somewhat chary of its employment Apicolysis, in my experience, has been disappointing, but I still hope that some improved method may yet be evolved, since the principle seems to be attractive and admirably adapted to the purpose in view Thoracoplasty in its modern forms has proved so valuable that it should always be considered in cases suitable for artificial pneumothorax when that form of treatment has proved impracticable The contraindications, however, are more definite and more emphatic than those of artificial pneumothorax

Phrenic evulsion is proving of great value, especially in preparation for, and in addition to, artificial pneumothorax in some cases where this procedure by itself is unsatisfactory I find it useful in some patients with unilateral disease where the localization is predominantly basal, though it is less often completely successful than might be expected

In abscess of the lung I wait till the abscess is definitely localized and then, if rupture does not occur, I call in the surgeon If rupture occurs, I try medical treatment, but if in six weeks it is clear that complete healing is not likely to occur, or if there are recrudescences of fever or expectoration, I recommend surgery A chronic abscess involves serious risks, notably those of secondary bronchiectasis, of cerebral abscess, and of progressive ill-health The longer operation is postponed the greater the risks I have been much impressed with phrenic evulsion as a means of effecting complete cure after thoracotomy and drainage, if residual cough and sputum are present

I have little experience of washing out the cavity through a bronchoscope, and I favour thoracotomy where possible

Bronchiectasis is a depressing and disappointing problem just now, both medically and surgically I hope that more may be done in the future to prevent it, since at present I am not too sanguine as to surgical procedures in this condition when it is fully established Phrenic evulsion in the early stage of unilateral cases certainly seems of value, and, if this fails, artificial pneumothorax or thoracoplasty is worth a trial Lobectomy seems to offer the greatest promise, but its risks are still serious

In malignant disease lobectomy is giving encouraging results in a small proportion of cases where the growth is localized in the lung parenchyma away from the hilum This should stimulate us to earlier diagnosis in these cases Improved means of applying radium may also shed more light on this dark corner of our work

Of empyema I should hesitate to speak were it not that the work of the American Empyema Commission does not even yet seem to have received general recognition, either by surgeons or by physicians Too early drainage of a streptococcal effusion leads usually to tragedy, which still too often occurs It cannot be too strongly affirmed that such an effusion should not be drained until frank pus is obtained on aspiration On the other hand, chronic empyema resulting from delayed or ineffective drainage is a serious reflection on medicine and surgery alike, and should be a rarity, which unfortunately it is not

Conclusion

In conclusion, I venture to hope that the present discussion will do much to stimulate a wider recognition of the achievements of thoracic surgery and of its benefits, but do nothing to stereotype surgical procedure or technique There is always scope for advance The surgeon is sometimes satisfied—the physician never We look to the surgeons to give us more and more effective help, and, judged by the rapid progress of the last ten years, I feel sure that the future is very hopeful

RADIUM IN CANCER THERAPY*

BY

DOUGLAS QUICK M.B., F.A.C.S.,

ATTENDING SURGEON MEMORIAL HOSPITAL NEW YORK

THE decade just passed, during which radium has come into a prominent position, has been an extremely active and interesting one in the cancer field. This has been due in part at least to the fact that radium and its allied physical agent the *x* rays, produce rapidly and readily demonstrable effects on neoplastic tissue. Cancer investigators have not previously had such a stimulus. In spite of the amount of investigation carried on for generations, improvement in cancer therapy was dependent almost entirely on technical surgical advances. Flurries of excitement have continued to centre transiently about alleged curative agents, usually of the constitutional type, but always with the same final result. The experience with radium and *x* rays on the other hand, has been one of increasing confidence over a period of years. New tissue changes have been produced, the study of which continues to throw light on the intricate and complicated reactions both histological and biological within that maze of allied disease covered by the term "cancer." Since most of the material for investigation has come through the treatment of patients scientific investigators have been brought out from the dark recesses of the laboratory and nearer, both figuratively and literally, to the practical clinical problems of cancer therapy. Even though the period of radium usage has been short, a great deal has been accomplished in very orderly sequence. The beginnings were made with small supplies of radium salt (frequently more of mesothorium than radium), meagre physical data and no single treatment factor standardized. An empirical technique was established largely by application of the law of trial and error. Filtered applicators for surface use and for introduction within body cavities were developed. The need for guidance by the physicist was recognized in this formative period, and that assistance has been most generously given. Fortunately for the general problem the physicist's contributions, although becoming increasingly complicated, have nevertheless remained extremely practical. A serious effort has been made to meet the clinical necessities.

As standards of filter and dosage became established for surface contact applications it was evident from both clinical and histological observations that greater quantitative effect at depth was essential. For superficial lesions this was obtained by increasing the distance between the source of energy and the treated part and by increasing correspondingly the quantity of energy delivered, according to the rule of the inverse square law. The quantities of radium available for use in most clinics at that time, however, were not sufficient to produce any marked effects at depth in bulky tumours of adult type or fully differentiated growth histologically.

In 1911 Stevenson of Dublin introduced an entirely different principle of radium therapy—one which has contributed largely toward the control of cancer as a local process since that time. By introducing a Dominici tube containing radium salt through a surgical incision as nearly as possible at the central point of the tumour he initiated the principle of interstitial irradiation. The method was sound both physically and economically. Technical improvement in the method, designed to accomplish interstitial irradiation with a minimum of surgical trauma, found expressions in various ways. For the many small radium supplies the radium element needle of varying strength, size, and filter was the most practical solution. In some clinics, particularly on the Continent and notably at the Curie Institute in Paris a larger type of needle with heavier filter and low radium salt content to permit of prolonged irradiation was preferred.

In America the clinics with sufficient radium supply to permit of a radium emanation collecting plant followed the suggestion made by Duane and initiated by Janeway at the Memorial Hospital in 1916—namely the interstitial implantation of glass capillary seeds containing radon. The practical collection and preparation of these seed was made possible by the work of Failla[1] who in 1924 replaced the unfiltered radon seeds by substituting a gold capillary tube. The filtered radon seed thus produced (0·3 mm. wall thickness of gold) had all the advantages claimed for the filtered radium element needles in addition to the extremely practical advantage of a wider range of applicability. It is the opinion of those who have had experience in the use of filtered radon seeds that they offer several advantage over element needles. The radon content of the individual seed may be varied to meet the peculiar requirements of the individual case. It can be inserted in many locations where element needles could not be retained with sufficient accuracy to permit of the desired prolonged irradiation. The accuracy of distribution in irregular tumour bearing areas is greater than with the larger needles. The trauma of introduction is less on account of their smaller size. Since they are left *in situ* the trauma of withdrawal is eliminated. Their reaction as a foreign body is negligible. The period of active irradiation—approximately a fortnight—is sufficiently prolonged on the basis of our present conception of the efficiency of continuous irradiation. The advantages in conjunction with operative surgery and primary wound closure are obvious since the seeds do not have to be removed.

With means available for more uniform and more intensive irradiation the earlier influence of *x* ray experience began to wane. The skin erythema, which had come to be regarded as an evidence of maximum irradiation intensity consistent with preservation of the normal tissue has gradually assumed the status of a unit of radiation. Over a period of years there has been a gradual trend away from the skin erythema as a dosage limitation. It has come to be a measure of quantity provided only that the factors of the exposure are known.

The steady increase in the relative *quantities* of irradiation employed has been accompanied and encouraged by the improved clinical results. These advances must, of course be shared with improvements in the quality of radiation used as well as the factors of time (period of exposure) and distance between the source of radiant energy and the part treated.

In more recent years the intensive histological study of tumour tissue before and after irradiation has contributed largely towards the advancement of radiation therapy. From the beginning very definite changes were noted but these centred mainly about effects on blood supply and the supporting structure of the neoplasm. The observations were sufficient to give some conception of the growth restraint produced. They explained the variation in response between widely differing type of tumours. They did not however explain the variations in response to comparable quantities of radiation in tumours of the same histological types. It remained for further studies in cellular pathology to clarify this.

Broder's work on the relative degrees of cellular differentiation in tumour of the same clinical and histological group not only explained the reason for many surgical failures but incidentally many unusual reactions to radiation as well. While the histological grading of tumour on the basis of relative degree of cellular differentiation must vary in different clinics it is nevertheless of considerable practical assistance. Each group of workers must have its own conception of what is meant by a certain grade one shades into the other. It is a piece of work which is scarcely capable of translation exactly from one clinic to another. Nevertheless the principle is the same and the differences in relative appraisal are not great. Information of this kind guide the clinician in determining the general character of the treatment to be given. Surgery is more apt to be resorted to in the fully differentiated tumour and avoided in the undifferentiated. The relative intensity of irradiation required varies inversely. The possibility or probability of metastases to be anticipated and the ultimate prognosis are judged to a considerable degree on the same basis.

The intensive histological study stimulated by radiation changes has made other contributions in the field of tumour pathology. New types definite clinical entities,

* A paper read in the Section of Radiology at the Annual Meeting of the British Medical Association Winnipeg 1930.

have been recognized The transitional cell carcinoma which Ewing[2] has described (and the lympho-epithelioma of Schmincke[3] and Regaud[4]) was formerly grouped with epidermoid carcinoma in general, or occasionally classed as a reticulum cell sarcoma until its peculiar radio-sensitivity resulted in its recognition as a type of epithelial tumour distinct both histologically and clinically Endothelial myeloma of bone—Ewing's tumour—was recognized in the same way after the study of a bone tumour which showed a peculiarly rapid regression, followed by regeneration of bone after moderate external radiation The large and varied group of soft part tumours of connective tissue origin formerly passed over as fibrosarcomas, or spindle-cell sarcomas is much better understood, owing to careful histological study in conjunction with irradiation They present a wide variation in cellular structure, and a corresponding variation in radio sensitivity All gradations in relative radio-sensitivity and radio-resistance are recognized, and must be used as a guide in selection of type and intensity of treatment The origin of the majority of this group of tumours from the nerve sheath has been one of the notable contributions of the study

With the accumulation of reasonably accurate and suggestive information about radio-sensitivity from histological study and clinical observations it was natural to inquire further into the factors of quality and intensity of radiation necessary to produce the desired changes

It is true that some of the most spectacular early results in radiation therapy were obtained by irradiation of low intensity with radium or *x* rays, and in such unstable tumours as lymphosarcoma and teratomas of the testis or ovary The most impressive histological changes, however, were in the more adult types of growth, and in order to produce these changes interstitial irradiation with radium or radon was the agent used When external radiation effects were studied, there appeared to be some difference in the reaction to comparable quantities of radium and *x*-radiation The fragments of evidence available suggested the possibility of more desirable effects from external irradiation if radium in sufficient quantity was employed

Observations at clinics, such as Kelly and Burnam's in Baltimore, and the Memorial Hospital, where radon packs have been employed for several years, lent support to this view Regaud's[4] method of prolonged distance radiation of low intensity also favoured radium as superior on account of the shorter wave-length of gamma radiation Economic factors have, unfortunately, made it impossible to provide a sufficient number of large radium element packs, in order that adequate external distance radiation may be carried on without regard for the expenditure of energy or funds in large numbers of patients

In those instances where adequate quantitative external radium radiation of maximum intensity has been possible, there is no doubt in the minds of the clinical observers of the superiority of radium over the most efficient *x*-radiation available to date This has been the experience of the Memorial Hospital staff during fifteen years' use of a large radon pack, an experience decidedly strengthened during the past three and a half years with a 4-gram radium element pack The total time of exposure undoubtedly contributed something toward this balance in favour of radium, but beyond this the main factor lies in the difference in *quality* of the radiation employed When the economic difficulties have been overcome, or when shorter wave-lengths of *x* rays equalling the gamma rays of radium in quality are produced for practical use, a tremendous improvement in practical radiation therapy will result The possibilities attendant upon total quantity per individual case, optimum period of total exposure, distance from source of energy to treated surface, and daily ratio of delivery of the radiation have not as yet been touched

It is only in this one field of external distance radiation that there has been any appreciable overlapping of radium and *x* rays Unfortunately, the number of cancer sufferers who have had the advantage of a superior quality of radiation, made possible by the extravagant use of large quantities of radium, represents only a negligible percentage of cancer patients in general In large measure the immediate advantages of this form of radium usage are academic rather than real The experience, however, points the way to more efficient radiation for the future It is hoped that means will be found to provide large quantities of radium for more general use It is hoped, also, that the experience already accumulated in favour of shorter wave-length gamma radiation will stimulate the engineers engaged in *x*-ray research and manufacture to provide equipment for *x*-radiation which will approach in quality the gamma rays of radium All of the available radium is needed for the type of application to which it is physically best adapted—namely, for interstitial implantation, and for use in various applicators within body cavities X-radiation should be the agent for external long-distance application—as it now is—but it ought to be of greater efficiency

Viewed in this light it is apparent that there is very little practical overstepping or duplication in the fields of radium and *x* rays, the two forms of radiant energy are very similar physically except for a difference in quality The character of the source of that energy in each instance governs the adaptability Radium is an agent for use over or within localized tumour-bearing areas, *x* rays are for use over large surfaces The two agents are complementary and not competitive Further, there is evidence in favour of the combined use of these two agents beyond that of simple physical adaptability Clinical and histological observations have been made on the difference in reaction with comparable quantities of the two types of radiation Clinical observations have been made on the improved therapeutic reactions where the two have been combined The experimental work of Quimby and Pack[5] has shown that when the two types of radiation are employed together and in equal quantitative ratio the skin tolerance, as judged by threshold erythema, is increased by 20 per cent or more

It is only recently that serious consideration has been given to the accurate study of the quantities of radiation delivered within the tumour-bearing area necessary to produce complete regression of tumour tissue Accuracy and standardization at every turn is essential if we are to develop a technique and dosage which may be depended upon to control a given type of growth and with a minimum of damage to adjacent normal structures Preliminary dosage was of necessity empiric Many factors enter into every dosage computation the character and quantity of energy in the applicator employed, the time of exposure, the filter, the distance from source to area treated, the relative distance of points on the periphery of the tumour from the radiation source, the character of the tumour bed, the type of tumour and its degree of relative cellular differentiation

With variations in each of the factors it was evident that any efforts toward greater accuracy and standardization must begin with one only At the Memorial Hospital, Martin and Quimby[6] undertook a study of the quantity of radiation necessary to produce complete regression of various types of epidermoid carcinoma A series of cases of intra-oral epidermoid carcinoma, in which complete regression of growth had been produced, was selected The histology of the growths was carefully re-checked for type and relative degree of radio sensitivity, the size of primary growth and metastatic nodes, if any, and the relative relationship of one to the other were noted The component parts of the radiation dose—*x*-radiation, external radium, and interstitial radon—were calculated physically in terms of threshold skin erythema doses within the tumour-bearing area In order to do this, for irregular-shaped growths particularly, it was necessary to translate the volumes into spheres or a series of smaller spheres, depending upon the shape of the growth, to get the dosage intensity at the most remote point of the tumour The intensity recorded was the minimum intensity at this most remote point Obviously a considerable portion of the growth received a good deal more than the recorded dose From a study of this series of cases it was found that an intensity of seven to ten skin erythema doses at all points within the tumour-bearing area was necessary to produce complete regression

of adult epidermoid carcinoma Cases showing a lesser degree of differentiation, such as transitional cell carcinoma and lympho-epithelioma, required a much lesser intensity —three to five skin erythemas

The tendency in these doses, selected empirically and on an experience basis only, was to overdose the smaller growth and to underdose the larger When a series of failures were measured in the same way the reason for failure in most instances was only too apparent The failure to provide dosage of sufficient intensity in the more bulky growths or in outlying areas accounted for most of the losses The next step was the application of the data thus obtained to the treatment of cases A series of cases of varied histological type were treated by calculating the dosage to begin with in terms of a certain number of skin erythema doses This intensity was determined on the basis of the histology and the experience gained from the studied series The method of delivery of this dosage was directed by the physicist on the most economic basis—*x rays, radium externally, or by interstitial implantation* The results in this series corresponded with the findings in the cases studied in retrospect It was found possible to depend on the result of treating a given area by this means of dosage calculation providing the measurements and clinical evaluation were correct and the technique of treatment, especially radon implantation was accurate It might well be added that control of local infection on ulcerating surfaces is essential if this or any other type of irradiation therapy is to be counted upon Doses for these cases in the last series, determined empirically and on an experience basis did not vary more than 10 per cent from the doses found necessary on the basis of measurement and physical and mathematical calculation

The work has demonstrated very conclusively that adult type epidermoid carcinoma requires seven to ten erythema doses throughout the tumour in order to ensure its complete control and that the undifferentiated types require at least one-half of this intensity This is of the utmost practical importance It not only explains the failures in bulky growths of this type where interstitial radiation was used, but too sparingly, but it indicates the futility of expecting complete control of epidermoid carcinoma by external irradiation alone in all except the most anaplastic growths at least with the present facilities and methods for external irradiation

The maximum dosage that can be delivered by external radiation within the oral cavity during a two- or three-week interval with our present equipment either *x* ray or radium and consistent with the tolerance of the patient, is at most, three skin erythemas of the intensities to which reference has been made Very few of the epidermoid carcinomas fall in the group sufficiently radio-sensitive as to be completely cleared up by three erythemas Consequently interstitial implantation in some form is imperative if clinical cure is to be accomplished by irradiation

With such data available it is unfortunate to see so many radiologists continuing to treat epidermoid carcinoma of the mucous membrane—*the most common* type of epithelial tumour—with *x* rays alone or, worse, with *x* rays and small plaques of *radium on the surface*

The most effective treatment of cancer by radiation methods is too complicated a problem for the radiologist to shoulder alone The same is true of the relationship of the clinician to the general management of the cancer patient The assistance of the pathologist and physicist is necessary in determining the treatment rather than when the therapeutic procedure whatever it may be, has been carried out The problem is one for group study throughout The best interests of the patient are served where the surgeon, *working in co-operation* with the pathologist and physicist, is thoroughly familiar with radiation, and thus combines the necessary operative surgery with the radiation therapy A more orderly and conservative co-ordination is thus attained than by transferring the patient from one department to another If this is not possible there should at least be the maximum of contact and co-operation between surgeon and radiologist The majority of cancer cases require in their total round of treatment, surgery radium and *x* radiation The more closely this is correlated the better

With the information—clinical, physical, and histological —accumulated to date to guide us, it seems proper to inquire into its practical application in radium therapy At least the limitations of radium application are better understood From a physical standpoint the intensity of irradiation is limited by tissue necrosis as a cauterizing agent radium is not justifiable Technically, the anatomical and physiological problems which limit operative surgery apply also in large measure to radium Damage to large blood vessels and nerves must be avoided In the upper abdomen physiological problems attendant upon intensive local irradiation require study before anything may be hoped for through the combination of operative surgery and direct radium radiation In spite of the benefits to be derived from radium therapy it must not be forgotten that it is a *local agent* The constitutional character of the later stages of cancer limits its use For the most part palliation in such cases is a medical and an *x* ray problem

In the major group of neoplastic disease the specific value of radium varies widely and its usefulness is dependent upon many factors Discretion must be made between efforts at cure and palliative relief only If a reasonable hope for clinical cure can be entertained, the maximum of intensity even though painful for a period is justifiable and desirable If palliation only is the object the patient's comfort from day to day demands first consideration, and the type and intensity of irradiation should be governed accordingly Radium may represent the sole therapeutic agent in certain instances or it may be only an associated aid in others Even within the individual groups the adaptability varies with the degree of growth advancement and the accumulated experience of radio-sensitivity or radio-resistance

The distinction between relative radio-sensitivity and curability should be clearly understood The most radio-sensitive tumours are those showing the minimum of cellular differentiation they melt away rapidly under heavy or even moderate external irradiation They also are of the type which disseminate early widely and usually through both lymphatics and blood stream While the local process may be readily controlled the tendency to generalization is such that the percentage of ultimate curability is very low It is also of interest that subsequent and repeated metastases show a progressive lessening in the degree of response to irradiation The patient's general physical resistance is of course deteriorated but added to this, the later metastatic processes show a tendency toward differentiation and are hence more radio-resistant While the primary fully differentiated epidermoid carcinoma is most difficult of all epidermoids to control the result, once attained is assured of a far greater permanence than in the more radio-sensitive undifferentiated types Real curability is greater in the more radio-resistant types

Rules for guidance in making the finer distinctions in choice of therapeutic procedures cannot be laid down Appraisal of the many factors entering into the decision is in the final analysis a matter of experience preferably co-operative group experience Whether that group represents a special clinic or simply a cancer service within a larger organization depends upon the local and individual circumstance

Skin cancer, unless extremely advanced or altered in its tumour bed by repeated recurrences is by choice a radium problem In all except the most superficial lesions heavily filtered radium at distances of one to three centimetres gives best results The wider zone of tissue radiated prevents recurrence at the border The penetration at depth is greater the scar is much better because of the lesser amount of fibrosis It is more adaptable to localized application than *x* ray and superior to thermic or electro-cauterization because of the wider zone of tumour bed affected

With carcinoma involving the mucous membrane of the mouth nose and throat the problem is much more complicated The growths are predominantly epidermoid carcinoma—a metastasizing tumour involving chiefly cervical nodes A variety of anatomical structures may become involved Infection may play a major part by

discounting the normal reaction to irradiation, and by contributing to secondary necrosis of tissue Problems of surgical drainage arise Invasion of bone or cartilage by tumour tissue or infection, or both, may add to the complications Interference with the taking of food or with breathing may arise Procedures for treating cancer under such varying circumstances differ, of course, in the various clinics These variations in procedure may depend upon the basic premisses accepted in the individual clinic, or be governed by the treatment facilities available

At the Memorial Hospital external radiation—radium or x rays, or both—is employed over both primary growth and cervical lymph nodes in all cases Radium, in the form of filtered radon by interstitial implantation, is depended upon for control of the primary growth Infection and tumour invasion of bone within the mouth or sinuses is a surgical problem The cervical nodes are left to external radiation unless palpably involved The palpably involved node of adult type epidermoid carcinoma, unilateral and with intact capsule, is treated by complete unilateral neck dissection, plus radon implantation within the wound in such fashion as to irradiate heavily any suspicious areas Bilateral involvements or nodes with perforation of the capsule by growth are treated by a combination of operative surgery with radium—surgical exposure under local anaesthesia and filtered radon implantation The metastatic nodes of undifferentiated growths are treated by irradiation entirely, even though technically operable Direct radon implantation is usually indicated, and to facilitate this surgical exposure is resorted to The treatment of intra-oral cancer affords the best and most varied example of the value of combining operative surgery and radiation in meeting the needs of the individual case

In some clinics with a limited radium supply, the practice of removing the primary growth surgically, usually by one of the cautery methods, and following this by radium needle applications, is prevalent From experience with radon implantation plus surgical removal in certain instances to overcome deep-seated infection, it would seem desirable to reverse the order of that procedure The condemned area might well be utilized as a radium needle holder, the growth devitalized before operation, and the adjacent tissues substantially irradiated preliminary to surgical traumatization

With extrinsic laryngeal cancer, treatment by irradiation, external and interstitial, is the only resource, except for the few highly radio-sensitive growths where x rays alone in maximum dosage may be sufficient to produce complete regression If broad surgical principles are adhered to, all of these growths are inoperable Intrinsic laryngeal cancer presents a different picture A certain percentage of these growths are surgically operable The anatomy of the parts facilitates removal by total extirpation of the larynx Metastasis rarely occurs until late in the course of the disease Under such circumstances the selection of treatment procedure becomes a matter of *preference In our clinic radium is employed through* choice In the majority of cases direct radon implantation, following heavy external irradiation, is carried out through the exposure by laryngotomy—again an example of combining a conservative operative procedure with irradiation for the purpose of greater technical accuracy

Continuing, the mucous-membrane-lined tract downward into the bronchial tree, oesophagus, and upper gastro-intestinal tract, leaves much to be desired from all forms of treatment, especially radium Few growths lend themselves to interstitial implantation anatomically, and the hazards of infection are great A considerable degree of palliative relief has been produced in these areas through the growth restraint induced by external radium or irradiation Further benefit lies probably in technical improvement of the methods of external radiation, except possibly in cancer of the upper gastro-intestinal tract This field ought to claim the sympathies and ingenuity of a master gastro-intestinal surgeon, willing to forgo some of his preconceived ideas, inform himself of the fundamentals of irradiation therapy, and thus combine forces in a new approach

In the rectum and lower bowel much has already been accomplished both curatively and palliatively by intensive irradiation with and without surgical co-operation, and is indicated by the special features of the individual case

Cancer of the female pelvic organs is extremely interesting radiologically In the treatment of cancer of the cervix uteri radium has achieved its most notable success It is the agent of choice The involved part is extremely tolerant of heavy irradiation, it is relatively insensitive to pain it is accessible Histologically, more than half of the growths are of the plexiform epidermoid type, showing a relative lack of cellular differentiation and hence radio-sensitive Historically, it is interesting to note that the gynaecological field was one of the first to employ radium, and this vision and courage on the part of a few pioneer gynaecologists did much to advance radium therapy to the position which it now occupies

Carcinoma of the corpus uteri differs from the cervix growth in histological type, in anatomical relationships, in accessibility, and in its mode of extension and dissemination Radium undoubtedly fills a useful place in early questionally malignant lesions and in advanced questionably operable cases In the intermediate, well-established group, however, hysterectomy is the method of choice

These two types of growth in the same organ afford a clear-cut and nice distinction in the choice of a treatment method

Growths of the external genitals, male or female, are for the most part epidermoid carcinomas, and hence are subject to the same general principles of treatment as epidermoid carcinoma elsewhere The same is true of bladder cancer, except for its inaccessibility The papillary type of epidermoid carcinoma predominating in the bladder is relatively radio-resistant, so that heavy irradiation dosage is necessary for its control In spite of this, direct exposure by suprapubic cystotomy and direct filtered radon implantation is preferable in most cases to the various operative procedures advanced

Cancer of the prostate may yield completely to interstitial irradiation, in any event a variable degree of growth restraint may be brought about Radium is, in general, the agent of choice, not because of the brilliance of the results, but because it accomplishes at least as much and affords greater palliation with less hazard than operative measures

Cancer of the breast represents one of the largest groups of malignant disease The histological types and variations are numerous Fat predominance in the tumour bed is not duplicated elsewhere Metastasis, whether by direct permeation of lymphatics or by showers of vascular tumour emboli, is early The tendency toward generalization of metastatic involvement is much greater than is ordinarily thought to be the case Metastatic extension beyond the axilla is not only surgically inoperable, but is so deep seated, as well as generalized, that it is radiologically inaccessible Breast growths, as a group, are relatively radio-resistant, not only on account of their histological *structure, but because they tend to infiltrate adjacent fat* tissue An active radiation reaction is difficult to produce in fat tissue, probably because of the limited blood supply and the tendency toward fat necrosis under the influence of heavy irradiation In spite of these discouraging factors, radiation has contributed much to the treatment of the breast group For widespread irradiation x rays are obviously the agent of choice For localized applications externally or for implantation, radium has its place

Pre-operative and post-operative irradiation is accepted as of distinct value, the former is preferred Questionably operable cases and breast cancer in the aged are better treated by irradiation than by operative measures The strictly operable group is thus sharply limited The palliative benefits of irradiation in breast cancer are probably greater than in most other groups The benefits of radiation are not limited, however, to palliation only The group of clinically cured cases, treated by irradiation only, is steadily increasing In certain instances this has been accomplished by heavy, prolonged external treatment For the most part, however, it has been in conjunction with some form of interstitial irradiation The measure-

ment of dosage intensities by Lee and Pack following the plan employed by Martin and Quimby in their dosage intensity calculations for intra oral cancer suggests the need for greater relative intensities in breast cancer than in mouth cancer They have demonstrated at the same time that these required doses of intensities, well beyond ten erythemas can be carried through practically Their minimum standards of intensity have not yet been determined, and it may be found that a very considerable percentage of the cases respond to a much lower relative quantity of irradiation

In the lymphatic, glandular neoplastic, and pseudo-malignant diseases—lymphosarcoma Hodgkin's disease and leukaemia—radium may be useful and is occasionally of real value for some specific reason In general, however, the widespread character of the involvement lends itself best to treatment by x radiation The treatment is palliative only

The bone tumour problem is as discouraging as it is fascinating Radiation has made but two distinct contributions attributable alike to either x rays or radium, or both Giant-cell tumours of bone are curable by external irradiation The peculiar response of endothelial myeloma of bone to radiation led originally to its recognition as a definite clinical entity, and irradiation has remained the treatment of choice The tendency to early and widespread dissemination of this growth however, renders cure extremely doubtful The true osteogenic tumours of bone are extremely radio-resistant and radium has done nothing more than afford a moderate degree of palliative relief and growth restraint

Summary

1 Radium has made a notable contribution and has added stimulus to the general problem of cancer investigation

2 Since it is an agent for local application only, it must not be regarded as an ideal cancer cure

3 It has, however, increased the curability of cancer

4 It has reduced the limits and the severity of many operative surgical procedures

5 It has supplanted some surgical operations entirely

6 It has relieved operative surgery of the responsibility for attempting the unreasonable or impossible, as a frantic effort in a large and varied group of cases

7 It has made possible a larger measure of palliative relief in advanced cancer

8 Advancement in radium therapy depends upon the intensive co-operation of pathologist clinician and physicist

9 The technical problems of application and dosage intensity must be calculated and made with the greatest possible care and precision

10 The combination of radium emanation, x radiation and operative surgery offers far more in the average case of cancer than adherence to any one agent alone they are complementary, and not competitive

"DECEREBRATE RIGIDITY" IN MAN

BY

J. S. MANSON, M.D. D.P.H.,

AND

FERGUS R. FERGUSON M.D., M.R.C.P., D.P.H.,

ASSISTANT PHYSICIAN MANCHESTER ROYAL INFIRMARY

(*With Special Plate*)

At the outset we wish to point out that although the title of "Decerebrate Rigidity" in Man" has been given to this short paper we have made the publication rather to encourage interest and observation in this subject and to relate a very interesting clinical case than to record a detailed clinico-pathological study for from this latter point of view, our records are incomplete

As Walshe[2] points out the variety of clinical features already included under this designation indicate that there has been no clear guiding conception of what a very definite condition true decerebrate rigidity is, and the term bids fair to become a vague label including all obscure forms of tonic spasm in a category which has a thoroughly false air of scientific precision

Experimental Decerebrate Rigidity

Since Sherrington[1] detailed his experimental results of transection of the brain stem of animals and described the resulting picture of "decerebrate rigidity" or "reflex standing" there has been considerable difference of opinion as to what clinical picture constitutes its counterpart in man

Experimental decerebrate rigidity occurs when the greater part of the anterior portion of the brain is removed by a coronal section through the hinder part of the mid brain, in a plane bounded dorsally by the posterior limit of the superior corpora quadrigemina and ventrally by the region immediately caudad to the corpora mammillaria This section cut off the greater part of the red nucleus from the body if the transection passes above the red nucleus the muscle tone remains normal Rigidity persists as the plane of the transection passes caudally through the pons and medulla to the level of entry of the acoustic nerves and Deiters's nucleus Thus the brain stem centres responsible for decerebrate rigidity clearly lie in the pons and medulla

In this experimental decerebrate rigidity there is a great increase of tonus in the extensor group of muscles with reflex inhibition of tonus in the antagonistic flexors in accordance with the laws of reciprocal innervation On being suspended the animal hangs with its fore limbs thrust backward with retraction at the shoulder-joint, straightened elbow, and some flexion at the wrist The hand of the monkey is turned with its palmar aspect somewhat inward The hind limbs are straightened and thrust backward the hip is extended the knee very stiffly extended and the ankle somewhat extended The tail is straight horizontal or stiffly curved upward There is a little opisthotonos of the lumbo-sacral region and the head is kept lifted up against gravity Sherrington regards this rigidity as reflex standing—the result of release or removal of inhibition of the postural reflex it can be abolished by section of the appropriate afferent posterior nerve roots

Decerebrate Rigidity in Disease

The problem is to ascertain what is the counterpart in man in a physiological sense, of this experimentally produced rigidity

Kinnier Wilson[12] has carefully analysed and recorded conditions—the results of cerebral haemorrhage meningeal inflammation or intracranial tumour—in which there has been coupled with the impairment of consciousness tonic rigidity of the trunk and limbs He considers that these clinical pictures minutely resemble experimental decerebrate rigidity In many of these cases frequent exacerbations are superadded in the form of tonic or postural fits accentuating and exaggerating the background of tonic posture The cases fall into three groups (1) decerebrate rigidity (or attitude) and tonic fits combined (2) cases of decerebrate attitude without tonic fits (3) cases of tonic fits without persisting decerebrate attitude Hughlings Jackson[3] described attacks of rigidity in cases of cerebellar tumour Many of these cases showed also tetanus-like seizures in which the patient exhibited opisthotonos with extension of the lower extremities and flexion of the upper extremities but he considered that the causation of the two conditions was different In Wilson's opinion the involuntary posture of a limb or segment of a limb in many forms of nervous disease as well as the transient positions assumed in involuntary movements such as chorea and athetosis are in reality simply parts of the complete decerebrate attitude

Walshe,[11] on the other hand, carefully studied the problem of Sherrington's decerebrate rigidity from the point of view of its occurrence and recognition in the human subject, and concluded that, while in the spasticity of hemiplegia and the paraplegia in extension, there is a clear example of hypertonus physiologically identical with that observed in the decerebrate animal, for the most part, the cases recorded as decerebrate rigidity in man are examples of different varieties of extrapyramidal syndromes or tonic fits, none of which can be identified with Sherrington's decerebrate rigidity. He recorded a case,[10] which he considered a closer approximation to the experimentally produced condition than any previously encountered. The patient lay motionless and unconscious on her back, with the head in the median position. There was no trace of head retraction. The arms lay across the chest, semiflexed at the elbows, with the forearms slightly pronated and the wrists and digits flexed. The legs lay extended and adducted, with the feet plantar flexed. There was spasticity of moderate degree in all four limbs, definitely more pronounced in the arms than in the legs. The tonus was plastic and "clasp-knife" in character. The tendon-jerks were all very brisk, the abdominal reflexes absent, and the plantar responses extensor. The tonic neck reflexes of Magnus and de Kleijn were also obtained.

There are two points of defect from the complete picture of decerebrate rigidity: the first, the flexion posture of the upper limbs, and the second, the retention of temperature control. The flexed position of the upper limbs may be traced to the fact that in man the fore limbs are no longer simple locomotor props, but have taken on new and highly complex functions under the influence of the cerebral cortex. In consequence, they would not be expected to take up the extensor attitude of standing. In this case, it was at the stage of failing reflex activity, when the phenomena of decerebrate rigidity were finally disappearing, that tonic fits and the accompanying respiratory and cardiac irregularities appeared. This was regarded as demonstrating the fundamental difference between tonic fits and true reflex decerebrate rigidity, and as showing that there was no correlation between experimental decerebrate rigidity and the types of muscular spasm seen in extrapyramidal syndromes. Post-mortem examination revealed a suprapituitary cystic tumour and a well-marked secondary hydrocephalus, pressure from these on the structures in the anterior part of the brain stem produced the effect of decerebration by cutting off the cerebral hemispheres from functional connexion with lower levels.

The anatomical site of the lesions in Wilson's cases, with extended neck and spine, adduction at the shoulder, extended elbow, internal rotation, hyperpronation and flexion of the wrist and fingers, was similar to that of experimental decerebrate rigidity. Wilson regards the two states as physiologically equivalent, whereas other observers regard the hemiplegic posture in man—that is, flexion of the upper and extension of the lower limb—as the equivalent of decerebration in animals. Brain[1] considers that these views are not mutually irreconcilable. He has observed, although it is not always easy to demonstrate, that an extensor attitude of the upper limb, which exactly reproduces the posture of this limb in a "tonic fit," can be reflexly evoked in a hemiplegia by making the patient assume a quadrupedal attitude. This posture is the normal quadrupedal standing attitude of the anthropoid ape when on all fours. On the other hand, the "hemiplegic" attitude of flexion of the upper with extension of the lower limb is the primitive erect standing attitude of our subhuman ancestors. Man has passed through two stages in evolution, the more primitive characterized by quadrupedal standing, the later by erect standing. Thus, if by decerebrate rigidity is understood the posture or reflex standing, man may exhibit two decerebrate attitudes—quadrupedal and erect—the former of which (the attitude of "tonic fits") is the pathological equivalent of decerebrate rigidity in animals.

It will thus be seen that the cases appearing under the heading of decerebrate rigidity in the literature present considerable variation in the type of tone in the posture assumed, and in the reflexes. Cobb,[2] Weisenburg and Alpers,[12] Zand,[14] and recently Epstein and Yakovlev,[4] have contributed, among others, to the literature on this difficult subject. In clinical practice, especially in children, cases are not rare in which the child is in such a fixed rigid attitude that it may be lifted into the vertical from the horizontal posture by placing one hand under the head. The actual position of the arms and legs in these cases varies considerably, but the type of tone increase appears to be more frequently extrapyramidal than pyramidal.

Notes on a Case

The following case was under the care of one of us (J. S. M.) for a period of ten years, and during the greater part of the time he lay motionless and speechless, like a log, with his arms adducted and flexed at the elbows and wrists, and his legs rigidly extended—in the position regarded by Walshe and others as the physiological counterpart of experimental decerebrate rigidity.

A. B., male, was observed in November, 1918, at the age of 67, to incline to the right when out walking. Early in 1919 he complained of stiffness in his left shoulder and pain in the left leg, so that he had great difficulty in dressing. He was treated at Buxton for rheumatism, but returned unrelieved. About this time he lost all interest in his business and in his surroundings, he was frequently disorientated as to time and place, and would hold the newspaper upside down, although apparently reading it. He slept readily, and did not now complain of pain. Early in 1920 he exhibited great emotional distress at the death of his son, aged 24. A neurologist saw him in April, 1920, and noted a peculiar stiffness and slight weakness of the left side of the body, with ankle-clonus and an extensor plantar response. He considered the condition to be due to cerebral arterio-sclerosis, with softening in the right internal capsule. A. B. became gradually worse, the right arm became stiff, and he was only able to walk about the room with great difficulty.

In 1921 he became bed-ridden, and his apathy to his surroundings was more pronounced. The lower limbs were rigidly extended, with marked exaggeration of the tendon reflexes, bilateral extensor plantar responses, and ankle-clonus; incontinence of urine and faeces supervened. He could still use his arms for feeding himself.

During 1922 his condition altered but little, he recognized his attendants, but seldom spoke. In 1923 he was unconscious for three days, and it was thought that he was going to die. Towards the end of the year his wife had a cholecystectomy performed, when she returned home early in 1924 and explained where she had been, he remarked, "You look as if you had had your wings clipped." He made no further remark, and lapsed into his usual silence and apathy. In June, 1924, the family moved to a house in a brighter and sunnier situation, but he made no comment, he was utterly indifferent and apathetic, the increase in tone in the upper limbs now became so marked that he had to be fed.

The years 1925 and 1926 passed without much change, except the increasing rigidity of all four limbs. The upper limbs were strongly adducted at the shoulders, semiflexed at the elbows, with pronation of the forearms and semiflexion of the fingers. The rigidity in the lower limbs was so marked that it was impossible to flex the limbs, and when an attempt was made to abduct one leg, the other followed in the same direction. There was some retraction of the head, swallowing was fairly good with slow feeding, and the ocular movements were apparently full. Trophic sores appeared on the left leg and foot in 1927, the pulse, at times, thin and thready, at times full and strong, varied in rate from 68 to 110. In 1928 his general condition deteriorated and his muscles wasted. He lay like a log, not speaking and apparently not recognizing any of those in attendance. His wife used to hear him mumbling in his sleep, but she could never understand what he said. It is interesting to note that in June, 1928, when one of his sons brought his 3-year-old twin daughters to see their grandfather, seeing one and not the other, A. B. said, quite clearly, "Where is the other?" He had not spoken since 1924, when he made the cryptic remark about the clipping of his wife's wings. He died on September 17th, 1928, at the age of 77, ten years after the onset of the first symptoms, and after having been bed-ridden and practically speechless for seven years.

In the post-mortem, permission was granted for the examination of the brain only. On removing the calvarium it was seen that the dura mater was thickened and excessively vascular in the right pre-Rolandic area, it covered, and was adherent to, a firm, rounded tumour, about two inches in diameter. The tumour had all the appearances of an endothelioma (growing from the falx cerebri). As is usual with these tumours, the surrounding brain tissue gave the appearance of having been hollowed out by the tumour. Beneath the tumour there was a softening extending into the basal ganglia, the medial surface of the oppo-ite

hemisphere showed the imprint of pressure from the tumour but the anterior cerebral artery was not occluded The ventricle in the left hemisphere was somewhat dilated there was no obvious softening in the left hemisphere and the pons and medulla appeared normal The cerebral vessels showed only a slight degree of atheroma The specimen was sent to Sir Arthur Keith and is now in the Royal College of Surgeons Museum (5918.2)

Microscopical examination confirmed the endotheliomatous nature of the tumour and showed *some degeneration in the pyramidal tracts* in the mid-brain and pons but not in the medulla oblongata

We regret that we have no notes of careful observations on the type of tone increase or of the tonic reflexes of Magnus and de Kleijn and other observations, which correlated with a complete pathological examination, would have made a very valuable record In view of the incompleteness of the clinical details, a complete serial sectioning of the mid-brain and pontine regions was not considered warranted

The early rapid progressive dementia and other unusual features encountered in this case in contrast with those usually found in a frontal endothelioma make it probable that a considerable portion of the symptomatology was due to cerebral vascular disturbances Jefferson,[6] in recording states of bilateral rigidity—which were accompanied by *'tonic seizures" consisting of sudden accesses of rigidity —in middle meningeal haemorrhage, regarded the generalized rigidity as the result of disturbance of a very fine* circulatory balance or a relative anoxaemia sufficient to suppress cortical control, but not great enough to render inactive the causal mechanism in the mid- and hind-brain

We would call attention again to the two apposite utterances in 1924 and 1928, which contrasted very strongly with his otherwise complete silence and apathy for about seven years It seemed that when an external stimulus was powerful *enough to revive a thought or idea to a certain* degree of intensity it could be expressed in spoken words It is interesting to speculate whether these gleams of comprehension could be explained by Spearman's theory of the two factors 'g" and 's'— 'g' representing the *'general mental energy, and "s" the special group of* neurones activated by that energy In A B the 'g" factor was too feeble as a general rule to activate any special group of neurones 's' to such an intensity that *utterance was possible*

Attention has been called again to the divergent views which are held as to what constitutes clinical decerebrate rigidity Can these views be reconciled Can we explain why these cases, which broadly might be described as being characterized by generalized rigidity, present such differences in the posture assumed and the type of increase of tone? In contrast to the case of A B recorded above one of us (F R F) has under his care at the present time a boy aged 12, *with the 'decerebrate attitude" picture* of Kinnier Wilson, probably the result of encephalitis He came under medical observation two years ago for attacks of falling backwards which were regarded as petit mal There was no loss of consciousness and his general and mental states were quite good At the present time (as he lies in bed) his head is lifted forward his lower back is slightly arched forward, his arms are extended adducted and pronated with slight rapid rhythmical tremor of the left hand The legs are rigid extended and the feet are markedly plantar flexed He moves very little voluntarily but can be lifted and turned like a 'plank of wood When placed erect he stands on tip-toes and would fall backwards if not supported His smile is slow stiff and spastic intelligence is practically normal There is *generalized muscular rigidity* The tone increase is of the typical cogwheel type and the limb assumes the posture *into which it is* placed for a few minutes before returning to the original position There is no reflex evidence of involvement of the pyramidal tract—the abdominal reflexes are brisk knee-jerks normal and plantar response flexor He shows the tonic neck reflexes of Magnus and de Kleijn From time to time he has "tonic fits" in which the abnormal posture is exaggerated

Wilson says "In the condition which has been regarded as decerebrate rigidity in man—that is one of complete interruption of function both cortico-spinal and strio-spinal produced by lesions of various kinds, roughly speaking at the level of the mesencephalon—what do we find? Since the striatal system is out of action, we might expect the universal rigidity of the post-encephalitic Parkinsonian but it does not develop Instead we get an attitude in extension which may fairly be regarded as indicative of an attempt at 'reflex standing' In other words the posture produced by release of function when both old and *new systems cease to act on the spinal neurones* simultaneously is that of release neither from the one nor from the other" From clinical data he has argued that the results of complete single release (hemiplegia and paraplegia) are not identical with those of complete double release (decerebrate rigidity) where both cortical and striatal efferent systems are affected It would appear that the resulting picture depends on the degree to which these two systems are affected and their relative importance in a particular subject—*animal or human, young* or old

It is hoped that the recording of this undoubtedly interesting clinical case will stimulate interest in the problem of 'generalized rigidity," and will lead to more complete examinations which in turn will help to solve the problem of the motor pathways and the lesions which result from disease of them In the current number of the *Journal of Neurology and Psychopathology* Carmichael has given *an excellent short account of a human mid-brain preparation*—the type of case to which generally little or no attention is paid from the point of view of scientific interest

Practitioners frequently have not the opportunity of reading the works of experimental physiologists and of studying posture in detail but it is hoped that by calling attention to clinical decerebrate rigidity we will give neuropathologists a better opportunity for studying the problems of the motor system in the light of accurate, full clinical histories and neurological examination

It is a pleasure to acknowledge our thanks to Dr E E. Bowden for his assistance in making the post-mortem examination and to Dr Cecil Beadles for his interest in the specimen and the accompanying illustration

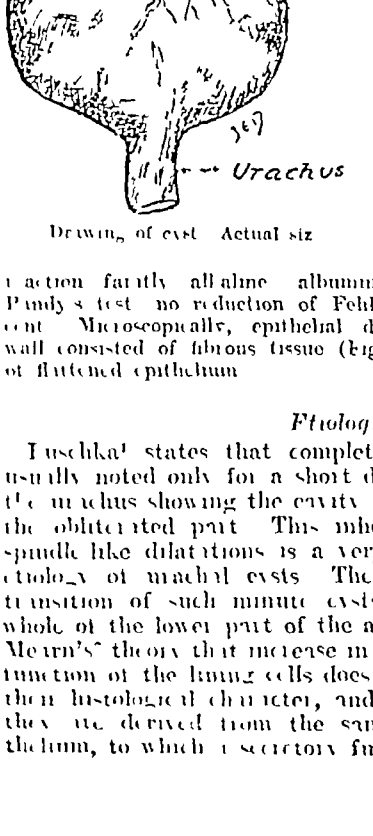
CYST OF THE URACHUS

BY

ARCHIBALD RONALD MD F R C S Ed

(*With Special Plate*)



Complexity of development in the lower urinary tract affords ample opportunity for the occurrence of congenital abnormalities Persistence of the intra-abdominal part of the allantois from the bladder to the umbilicus as a patent urachus or the imperfect obliteration thereof with cystic formation are among the less common varieties Urachal cysts attract attention either from their increasing size or from the advent of infection Some cases are discovered accidentally either at operation or at autopsy The case reported below was unsuspected prior to operation The patient a young adult male, aged 26, had not suffered from any previous illness

Report of Case

About one year before admission the patient experienced attacks of 'sharp' pain in the right iliac fossa. The pain persisted for three to four hours. After an interval of five or six months the attacks recurred and were of greater severity. Local applications of counter-irritants failed to relieve his symptoms, and he was referred to the out-patient department of the Royal Albert Edward Infirmary, Wigan. At that time examination revealed slight tenderness on deep pressure in the right iliac fossa, and a diagnosis of mild appendicitis was made. A radiographical examination after a barium meal showed some delay in the ileo-caecal region.

The patient was admitted two weeks later. He then had pain before or after meals, the appetite was good, and the bowels slightly constipated. The anterior abdominal wall moved freely on respiration. There was no irregularity of contour. Palpation revealed slight deep-seated tenderness in the right iliac fossa. No abnormal mass was detected. No pain was associated with micturition. There was no haematuria, but slight frequency by day was present. Urine: sp. gr. 1024, reaction acid, albumin and sugar absent.

Operation.—May 9th, 1929. The appendix was delivered through a gridiron incision, and showed a sharp kink about one inch from its base. At the angle it was unduly firm to the touch. The appendix was removed. Exploring further, the examining finger came into contact with a soft rounded swelling fixed to the anterior abdominal wall midway between the umbilicus and the pubis. The tumour was pulled into the wound and was found to be lying extraperitoneally. By dissecting the peritoneum off the anterior abdominal wall, the tumour was mobilized and delivered. The cystic character of the tumour was at once apparent, and its position suggested its urachal origin. Attached to and blending with the poles of the cyst were two rounded fibrous cords. The lower could be traced to the apex of the urinary bladder, and traction on the upper demonstrated its attachment to the umbilicus, and at the same time brought into view the two obliterated hypogastric arteries converging on the urachus as it passed towards the umbilicus. The urachus was ligated above and below the cyst and divided. Recovery was uneventful.

Drawing of cyst. Actual size.

Further questioning after the operation failed to elicit any additional urinary symptoms, and cystoscopic examination did not reveal any abnormality of the bladder.

Specimen.—The cyst was of the shape shown in the drawing reproduced herewith, and measured 5·5 by 3·5 cm., 24 c.cm. of colourless, slightly opalescent fluid were withdrawn from the cyst, and the tests showed the following: sp. gr., 1014, reaction faintly alkaline, albumin, trace; globulin, trace; to Pandy's test no reduction of Fehling's solution; urea, 0·25 per cent. Microscopically, epithelial debris was found. The cyst wall consisted of fibrous tissue (fig. 1), lined by a single layer of flattened epithelium.

Etiology

Luschka[1] states that complete closure of the canal is usually noted only for a short distance above the bladder, the urachus showing the cavity again for 5 to 7 cm. above the obliterated part. This inherent tendency to develop spindle-like dilatations is a very important factor in the etiology of urachal cysts. The exact mechanism of the transition of such minute cysts into tumours filling the whole of the lower part of the abdomen is not quite clear. Mearn's[2] theory that increase in size is due to the secretory function of the lining cells does not seem in keeping with their histological character, and from the knowledge that they are derived from the same source as bladder epithelium, to which a secretory function is never attributed, Binnie[3] has given an explanation which might hold good in a few cases—namely, persistence of communication with the bladder associated with some obstruction to the outflow of urine causing dilatation of the lumen of the urachus. Later, from pressure and inflammation around the neck of the patent urachus, stenosis occurs and a permanent tumour is produced.

The condition is usually detected between the ages of 20 and 40 years, females are affected in the ratio of 3 to 1, but under the age of 15 years the sexes are equally affected.[4]

Pathological Anatomy

The urachus lies pre-peritoneally, and cysts arising from it have a similar relationship to the peritoneum. Cysts of the urachus vary in size from a few millimetres in length to cysts of enormous size, filling the whole of the lower abdomen and pelvis. The smaller cysts show remains of the longitudinal muscular coat of the normal urachus and are lined by transitional epithelium. In the larger cysts the wall is mainly fibrous tissue, and the lining a single layer of flattened epithelial cells. The foetal urachus is lined by several layers of epithelium, and in sections the lumen appears occluded with cells (Fig. 2).

Diagnosis

Urachal cysts are of little surgical importance except when very large or in the presence of secondary infection. Davis[6] pointed out that small cysts will elude the ordinary clinical examination. Cysts of moderate size are palpable below the umbilicus, sometimes slightly to one side of the mid-line, as rounded tumours which move freely from side to side more than up and down. In a patient with a lax abdominal wall a fluid thrill may be detected. Large cysts closely resemble ovarian cysts, and in the majority of cases will be indistinguishable from them. Movement of the tumour from side to side is likely to produce indrawing of the umbilicus in urachal cysts. The differential diagnosis must be made from distended bladder, ascites, ovarian cyst, and localized tuberculous peritonitis. At operation the extraperitoneal situation and connexion with the bladder make the diagnosis obvious.[5]

There are no symptoms referable to the cyst except when it is very large, or from the presence of complications. Pain arises from associated peritonitis. Slowness of micturition has been noted,[7] and also gastro-intestinal disturbances (Ulitz).

Complications

Sepsis is of frequent occurrence in the larger cysts. Haemorrhage into a cyst may bring about a sudden and rapid increase in size, with pain and tenderness. Peritonitis seems to be the rule when a urachal cyst has reached proportions sufficient to give rise to symptoms leading to its detection.

Treatment

Complete removal of urachal cysts can usually be accomplished without opening into the peritoneal cavity; in the infected cysts, however, the peritoneum may be so adherent to the posterior aspect that this cannot be accomplished, and some difficulty may be experienced in closing the resulting gap in the peritoneum. Marsupialization has proved very unsatisfactory. A paramedian incision lessens the risk of opening into the cyst. In view of the possible presence of a lumen in the lower urachal segment, simple ligation and touching of the stump with pure carbolic acid is indicated.

I am indebted to Mr. Fraser for permission to publish this case, and to Dr. W. E. Cooke and Miss Dyson for their assistance in the preparation of sections and diagrams.

ORGANIC GASTRIC SYPHILIS

BY

DAVID SMITH, M.D. F.R.C.P.S.

ASSISTANT PHYSICIAN ROYAL INFIRMARY EDINBURGH

(*With Special Plate*)

Organic gastric syphilis has received very little study or attention in Great Britain. This is due in no small degree to the rarity of the condition and to the difficulty of obtaining confirmatory pathological evidence. The sceptic is apt to say that the lesion is a coincidence *and is simply* some recognized condition occurring in a syphilitic patient. *On this account it is all the more necessary* for a definite diagnosis to be established between gastric symptoms occurring in a syphilitic subject and actual syphilis of the *stomach. It does not necessarily follow that every patient* with gastric symptoms and a positive Wassermann reaction *is suffering from organic gastric syphilis, even if an organic lesion can be demonstrated. It must be remembered that* both ulcer and neoplasm occur in syphilitic patients far more frequently than gumma does. Reference to the work of Chiari[1] and of Crohn[2] proves this.

History of the Disease

In previous cases which have been recorded the diagnosis was made from the fact that other specific lesions were present along with gastric symptoms, and because these cleared up under antisyphilitic treatment the diagnosis of "syphilis of the stomach" was made. I do not dispute the probability of the diagnosis being correct, but it is at *least controversial.* Into this category I put such cases as those described by Andral[3] as early as 1834 and which Monad[4] considers indisputable. The cases may have been syphilitic, but I *cannot hold the opinion expressed by* Monad that they are indisputable because there are no data *beyond the clinical history and the results of treatment to* warrant the diagnosis. I admit that at that time no further data such as x-ray examination and Wassermann reaction could be given, but without such investigation no case can be considered indisputable.

Up till 1907 several cases of gastric syphilis were recorded by Continental authors, but proof is lacking that these cases actually showed syphilitic gastric lesions. At this date Pater,[5] in a thesis, reviewed the then existing data, and also discussed 122 cases, rejecting those which did not present microscopical evidence of syphilis. He thus established the fact that cases with gastric symptoms sometimes have syphilitic lesions of the stomach. Since 1907 much has been written regarding syphilis of the stomach, but these contributions to medical literature have been made *mostly by American and* Continental writers. The majority of these records are based on radiography, the presence of syphilitic lesions elsewhere, a positive Wassermann reaction, or the results found at autopsy or operation. In 1912 Meyers[6] reviewed fifty-eight cases and the American literature has been added to by McNeil,[7] Morgan,[8] Downes and Le Wald,[9] Smithies,[10] Niles,[11] Easterman,[12] and others. Easterman's contribution is on twenty-three cases, and he reviews the literature. He establishes a sound case from the clinical standpoint. From the literature and the cases I have seen I consider that syphilitic lesions of the stomach can and do exist. This is confirmed beyond all doubt, and with a certainty that should dispel all doubts by McNee[13] who demonstrated the spirochaete in the lesion. Apart from this British literature contains nothing but adverse criticism of the subject, with the exception of the cases referred to by Hurst[14] Fenwick,[15] and Sherren.[16] Muir[1] states that 'syphilitic lesions, though rare, occur both in the congenital and acquired forms of the disease.' Bennett[17] admits that gastric syphilis does occur and urges that "whenever one is confronted with a case of organic gastric disease the possibility of syphilis must be remembered." Weir[18] reluctantly accepts the possible diagnosis and in spite of a degree of scepticism he states the case convincingly from the clinical standpoint. I cannot agree with his concluding remarks however that "the treatment of this disease is far from satisfactory, and that it may properly be argued that its almost uniform refractoriness to recognized antisyphilitic methods is evidence of some weight that many or most of the cases so diagnosed are not in fact, specific." The cases about to be described are in striking contrast to this statement.

Clinical Aspect

I wish to focus attention on the clinical aspect accepting the fact that pathologically and bacteriologically syphilis of the stomach is proved beyond all doubt, and therefore a clinical diagnosis should be possible and should be looked for oftener than it is. I do not hold the view that this diagnosis should be made because the Wassermann reaction is positive in a gastric case and because symptoms clear up under antispecific treatment. It is a well-known clinical fact that diseases which cause a general constitutional disturbance frequently give rise to gastric symptoms, and these improve or get well with the increasing well-being of the patient. I do not propose to deal with the cases discovered at operation or at autopsy, because, strictly speaking, such are not in the province of the physician. I wish, however, by recording six cases which in my opinion, are indisputable, to draw attention to the fact that syphilis of the stomach does occur, and that it can be cured by medical means, thus saving the life of the patient or averting operation.

Essentials of Diagnosis

Before deciding that a patient is suffering from organic syphilis of the stomach the following points have to be satisfied:

1. Symptoms definitely pointing to disease of the stomach or duodenum must be given.
2. X-ray examination must show evidence of such disease.
3. The Wassermann reaction must be positive.
4. The symptoms must not yield at all to a "try-out" of recognized treatment for peptic ulcer.

Proof of the cases being genuine is furnished if:

1. Symptoms clear up rapidly under light or ordinary diet in conjunction with intensive antisyphilitic treatment.
2. X-ray examination shows improvement or recovery.
3. The Wassermann reaction becomes negative or less positive.

It will be observed that confirmation of the diagnosis in the cases is obtained by assuming that the lesions are probably neoplastic, inflammatory, or ulcerative conditions in otherwise syphilitic subjects.

Review of the Cases

The cases I describe were put on strict treatment in bed and the results were observed. No improvement took place after four weeks of treatment, *and further x-ray examinations* show the conditions unchanged. The patients were, with two exceptions, allowed up on full diet and treated with neokharsivan, potassium iodide *and mercurial inunction*. In periods varying from seven to twenty-one days symptoms had disappeared and improvement in their general condition had begun. Treatment was continued and the final x-ray photographs were taken as an indication of cure or very marked improvement. The patients are still well at the end of periods varying from one and a half to five years, and no further treatment has been given. Case 1 died of pneumonia three years after. During that time he remained well. Unfortunately no autopsy was allowed.

I am going to consider six cases only because in these no other lesion due to syphilis was *found after thorough investigation*. Five were males and one was a female. This corresponds roughly with the incidence in the sexes noted by *American authors*. The youngest patient was a man aged 36, and the oldest a woman aged 60. Mauri[1] records a case in a lad, aged 19. Two of the male patients admitted infection, one twenty years and the other two years previously. According to Meyers[6] the alimentary lesion may appear as early as *ten months after infection* or as late as twenty-five years. None of the other patients admitted syphilitic infection and no history could be obtained of a *definite primary sore*, except in the

two patients who admitted infection, no secondary or tertiary symptoms or signs were admitted All six patients had + + or + + + Wassermann reaction The shortest duration of symptoms was six months, and the longest eighteen months The symptoms were progressive from the onset

Symptoms

The most frequent symptom is constant pain referred to the upper abdomen The character of the pain varies from a mild discomfort to agonizing cramp-like seizures, which are superimposed on the general distress in the upper abdomen and come on some hours after food These seizures are not relieved by taking food, but are somewhat relieved by vomiting The underlying general distress is not at all alleviated by vomiting In all cases the pain, whatever its character may be, is progressive, and the periodic remissions so frequently met with in gastric and duodenal ulceration are absent In character, therefore, it more closely simulates the distress of gastric carcinoma Nausea and vomiting are frequent symptoms The vomitus does not contain blood so often as it does in carcinoma and only one of the cases showed melaena Rehfus[21] records four cases where blood was present more or less persistently in the gastric contents Other observers have recorded fatal haemorrhages Anorexia is common, and this, with the constant vomiting, leads to loss of weight, marked anaemia, and some degree of cachexia The anaemia is often extreme, although there is no apparent loss of blood Cachexia is not so marked as in cases of carcinoma Jaundice occurs, but although I have seen several cases of this type I have not included them in this series

Physical Signs and Gastric Analysis

Physical examination of the abdomen may disclose a distinct mass caused by gummatous tumour formation in the intra-or pyloric regions This was well marked in two of the cases here recorded There are, however, no physical signs peculiar to organic gastric syphilis

Achlorhydria was demonstrated in five out of the six cases The lesion in the case which showed free hydrochloric acid was a gummatous mass causing pyloric obstruction This is in agreement with the findings of Downes and Le Wald[9] In this case there was almost complete retention of the gastric contents and it was in marked contrast to the other cases, where the gastric contents left the stomach rapidly There was no excess of mucus in any of the cases Blood and lactic acid were absent, the analysis depends to a great extent on the situation and type of the lesion, and may be influenced by the general debility and anaemia due to the syphilitic infection, for syphilitic anaemia generally shows an achlorhydria Some authors contend that the syphilitic virus in addition to the localized lesion may produce a general gastritis which is more responsible for the achlorhydria than is the lesion itself This is rather negatived in the cases here recorded by the fact that no excess mucus was demonstrated Crohn[2] thinks it is unlikely that any particular form of gastritis exists in these cases to a degree sufficient to cause an atrophy of the mucous membrane and a resultant anacidity or achylia gastrica Section of the mucosa away from the actual gummatous area fails to show any unusual form of gastritis The cells and membrana propria are not materially altered

X-ray Appearances

There is no definitely diagnostic x-ray picture of gastric syphilis The situation and character of the lesion in the individual case resembles a stenosis, an ulcer, a filling defect, or an infiltration

Diagnosis

The diagnosis must be arrived at by careful consideration of all the available data A purely clinical diagnosis is almost impossible, but in patients who give a history of definite gastric symptoms, especially when combined with achlorhydria, a careful examination of the blood, and if necessary the cerebro-spinal fluid, should be carried out with a view to ascertaining the Wassermann reaction As previously pointed out, we must not accept that organic syphilis exists even when x-ray deformities are found combined with achlorhydria and a positive Wassermann, for cancer and ulcer are far more likely to be present, the final word rests with the result of treatment Anaemia and cachexia are rarely so marked as in carcinoma showing somewhat similar lesions Sometimes syphilitic stigmata elsewhere will help in forming an opinion, although in the present series no such stigmata occurred, the absence of metastasis may help in differentiating syphilis from carcinoma

Owing to lack of space the x-ray plates before and after treatment have been omitted in Cases II and III They were easy of description, and this has been made in the text

Summary of Cases

Case I

Male, aged 57, ex soldier For one year complained of a constant gnawing pain in the epigastrium and left hypochondrium The pain was not much affected by taking food, and was not aggravated by a change from a light to a heavy diet He frequently vomited after meals, but without relief of pain The pain was severe at night, but was not helped by taking food His appetite was poor, and he lost 3 st in weight during the year He never noticed any blood in the vomitus, or darkening of the stools No previous serious illnesses, and denied syphilis Social condition good He took no alcohol, and smoked in moderation

On examination he was cachectic Cheeks were sunken, and he looked emaciated, abdominal wall sunken, no tumour palpable, no tenderness, recti tense, especially on the *left side*, *slight* discomfort on palpating the left hypochondriac region, tongue clean, teeth bad, constipated, no enlargement of liver or spleen, all other systems healthy No free hydrochloric acid was present, no lactic acid, no blood, no excess of mucus Wassermann reaction + + +, after treatment + − X ray examination showed filling defect and infiltration of the stomach wall, especially the greater curvature

Figure 1 (see Plate) shows the condition *before* and *Figure 2* after treatment

Case II

Male, aged 38, miner For eight months the patient complained of constant discomfort in the epigastric region The discomfort became actual pain about one and a half hours after food At irregular intervals he was seized with agonizing pain, which required morphine to relieve it, and the distribution of the pain suggested a gastric crisis Vomiting frequently followed this agony and gave relief, but the epigastric discomfort still remained There was no marked difference between night and day symptoms His appetite was poor, and he lost 2 st in weight during eight months No blood in vomitus and no melaena, no previous serious illnesses, and denied syphilis Social condition good He took no alcohol, and smoked in moderation

On examination he was *pale and emaciated* Abdominal wall tense, palpable tumour in the pyloric region, marked tenderness over upper right rectus in the area of the palpable mass, succussion five hours after food, tongue clean, teeth good, no constipation, no enlargement of liver or spleen, all other systems healthy Excessive resting juice, moderate mucus, high free hydrochloric acid, no blood, no lactic acid Wassermann reaction + + +, after treatment − X ray examination showed almost complete pyloric stenosis Practically no barium *had left the* stomach in five hours One month after treatment was begun x-ray examination showed that much of the barium had left the stomach in five hours, and there was only a small residue Unfortunately this man had to go abroad, and further plates could not be obtained The tumour could not be palpated when he left, and he had no symptoms The stomach was emptying better, and showed greater motility Treatment was continued, and he is still well at the present date, five years afterwards

Case III

Male, aged 53, steel worker For one and a half years complained of flatulence three hours after food The flatulence was relieved by taking food, but he was left with a feeling of weight in the epigastrium and right hypochondrium At times he had acute pain, which was confined to the upper abdomen The pain did not seem to have any relation to food, and sometimes came on during the night He vomited now and again, and sometimes this gave partial relief There was never any blood in the vomitus On more than one occasion he had melaena His appetite was poor, and he lost weight to the extent of 2½ st No previous serious illnesses Admitted having had syphilis twenty years previously Social condition good At one time took alcohol to excess, but for five years had been teetotal Smoked in moderation

On examination he looked pale and ill he appeared to have lost weight although not definitely emaciated abdominal wall tense no palpable tumour marked tenderness over right rectus from the costal margin to the level of the umbilicus no succussion tongue clean edentulous very constipated no enlargement of liver or spleen all other systems healthy No free hydrochloric acid mucus normal no blood, no lactic acid Wassermann reaction ++ after treatment – X ray examination showed marked duodenal deformity which entirely disappeared after six months treatment

CASE IV

Male aged 35 sailor For six months complained of pain three to four hours after food Relieved by taking food Nocturnal pain frequently present and relieved by taking food Pain was agonizing and sometimes required morphine to relieve it There was in addition to this pain a constant aching in the epigastrium and right hypochondrium He vomited frequently without relief No melaena and no blood in vomitus Appetite poor and he lost 2 st in weight No previous serious illness He admitted having had syphilis one and a half years previously for which he had some medical treatment but no injections Took no alcohol but smoked heavily

On examination he was cachectic He was very weak and appeared ill The condition of the skin pointed to marked loss of weight Abdominal wall tense no palpable tumour marked tenderness over right rectus from the costal margin to the umbilicus no succussion tongue clean very constipated liver and spleen not enlarged all other symptoms healthy No free hydrochloric acid mucus moderate no blood no lactic acid Wassermann reaction +++ after treatment – X ray examination showed irregularity of filling of lower part of the body of the stomach and duodenal deformity

Figure 3 shows condition before and Figure 4 after two and a half months treatment

CASE V

Female aged 60 housewife For one year complained of increasing pain in the epigastrium The pain was constantly present and was not affected by taking food She frequently vomited but without relief of pain At times she had agonizing cramp-like seizures in the right epigastrium and hypochondrium suggestive of gall bladder colic Appetite poor and she became bed ridden on account of weakness due to emaciation She was literally skin and bone She did not know how much weight she had lost but it must have been considerable No blood present in the vomitus no melaena no previous serious illnesses denied having had syphilis Social condition fair took no alcohol and did not smoke

On examination she was markedly cachectic-looking and very emaciated. Abdominal wall lax and sunken There was a visible tumour extending from the middle line well into the right hypochondrium. It moved slightly with respiration It was slightly movable on palpation and not particularly tender Tongue clean edentulous constipated no enlargement of liver or spleen all other systems healthy No free hydrochloric acid mucus scanty no blood no lactic acid Wassermann reaction ++ after treatment +– X ray examination showed filling defect in the antrum. Surgeon's opinion inoperable carcinoma

Figure 5 shows condition before and Figure 6 after treatment

CASE VI

Male aged 54 labourer For one and a half years complained of constant dull pain in the left epigastric region and left hypochondrium The pain frequently became acute almost immediately after taking food Vomiting occasionally took place The vomitus never contained blood and there was no melaena Sometimes the acute pain lasted for a day or two at a time Appetite poor and he generally felt weak He lost 2½ st in weight in a year He had had no previous serious illnesses and denied having had syphilis Social condition poor Moderate drinker and smoker

On examination he was cachectic and emaciated There was definite tenderness in the epigastrium one inch above the umbilicus and diffuse tenderness into the left hypochondrium Tongue clean teeth bad no constipation no enlargement of liver or spleen otherwise healthy No free hydrochloric acid moderate amount of mucus no blood no lactic acid Wassermann reaction +++ after treatment – X ray examination showed definite ulcer on the lesser curvature

Figure 7 shows condition before and Figure 8 after treatment.

Prognosis

The prospect of cure in cases of gastric syphilis is good, provided intensive treatment is employed This is true of all the cases recorded here even where a palpable mass has been present Improvement takes place almost at once, and within six months the most obstinate case failed to show physical or x ray evidence of disease Most of the cases were negative on examination at the end of two to two and a half months In this I agree with Einhorn[23] who records a case with a palpable tumour which yielded to treatment in six weeks Le Wald[24] on the other hand, thinks that beneficial end results are slow, and records a case which took nine years to bring about return to excellent health The general opinion is that the condition is capable of cure or marked improvement Eusterman[12] states that the total cured and improved is 69 per cent and that treatment instituted during the exudative stages gives brilliant results

Treatment

Treatment can be ambulatory, unless the physical condition of the patient is too low Food should be given in a manner that will not irritate the stomach but almost any kind of food can be taken Meat should be minced fish and fowl creamed fruit and vegetables given as purees and bread, etc, should be toasted so as to be crisp and require mastication If these points are attended to I do not think the nature of the diet requires any further attention Neokharsivan in doses varying from 0·3 gram to 0·9 gram is given in one, two, or more courses, as the individual case requires Potassium iodide has a marked effect and doses up to 30 grams three times a day should be administered Mercurial inunction should also be freely used Patients appear to stand the intensive treatment well, and no trouble of any kind was met with Iodide and mercury should be given, with short periodic rests, even after physical signs and symptoms have disappeared

Summary and Conclusions

1 Syphilis of the stomach, though rare, does exist and in searching for a diagnosis should be considered oftener than it is

2 Six cases are recorded of which four denied having had syphilis, so that denial of a primary infection should not exclude the possibility of the diagnosis

3 In most cases the disease is characterized by continuous pain, which is progressive, and has superimposed on it other pains of varying type

4 Vomiting is frequent and haemorrhage rare

5 A palpable tumour is sometimes felt and there is marked loss of weight and moderate cachexia

6 Definite x ray deformity is seen and gastric analysis shows an achlorhydria, except where there is pyloric stenosis

7 Syphilis should be considered in all atypical cases of gastric disease, or where ordinary methods of treatment fail

8 Prognosis is good

9 Treatment should be intensive

10 The diagnosis is confirmed by the results of treatment

I should like to thank Dr John Henderson in whose ward some of the cases were treated and Dr A Bruce MacLean to whom I am indebted for the x ray photographs

A LARGE CYSTIC TUMOUR OF THE SOFT PALATE

BY

J. J. C. McGIBBON, M.B., B.S., D.L.O.,

ASSISTANT SURGEON, LIVERPOOL EYE AND EAR INFIRMARY

(*With Special Plate*)

The following notes describe a large unilocular cystic tumour which was removed from the soft palate. Microscopically this tumour had the appearance of an angio-endothelioma, *but clinically the findings suggested a mixed-cell tumour.*

The patient, a man aged 57, was sent to the laryngological department of the Liverpool Eye and Ear Infirmary complaining of a lump in his throat. He stated that he had noticed a small swelling in the left side of his throat when on active service in 1915. The swelling had been constantly present since that date and had increased gradually in size during the past fourteen years. The lump had never been painful until it was punctured at another hospital four weeks previously.

On examination there was a large swelling about the size and shape of a hen's egg, almost completely filling the oropharynx. This tumour appeared to occupy the left half of the soft palate, pushing forward and to the right, and to extend from the junction of the hard and soft palates above to the level of the base of the tongue below. There was a small chink between the right tonsil and the tumour into which was crowded the uvula. *The mass was fixed firm, and painless on palpation, and the covering mucous membrane was normal.* His nose appeared healthy and the accessory sinuses clear. *It was mechanically impossible to examine the larynx or nasopharynx, the latter however was not seriously encroached upon, as nasal respiration was quite free.* The neighbouring lymphatic glands were not palpable.

X-ray examination by Mr. Thurstan Holland showed no bony involvement, the Wassermann reaction was negative. The provisional *diagnosis was mixed-cell tumour of the palate.*

The tumour was removed under open ether anaesthesia by blunt dissection. A good approach was afforded by the Boyle-Davis gag. Incision over the tumour exposed a bluish capsule which was *planted* without difficulty except at the post-rior and inferior poles. During the later stages of the dissection the capsule was ruptured accidentally and about two and a half ounces of straw-*coloured fluid* escaped. Haemorrhage was only slight. The wound was sutured and drained at its lower end. The left tonsil became *apparent then for the first time as a small flattened plaque.* The tumour when excised was seen to consist of a large cyst with solid tumour formation at its lower and posterior parts, and to contain numerous large friable intracystic papilloma-like structures. The patient made an uneventful recovery, and two months later the soft palate appeared symmetrical, was of good mobility, and functioned normally.

Dr. Hugh Smith, pathologist to the hospital, reported as follows:

Macroscopic

A cystic tumour about the size of a large tangerine orange. *Upon section it shows a wall of a uniform thickness of about a quarter of an inch and filled with intracystic growths which are very friable.* About two drachms of straw-coloured fluid was also present, but more of this was lost in rupture of the cyst during enucleation. The outer wall is smooth, except at one small area, at which point it had been adherent to surrounding tissues.

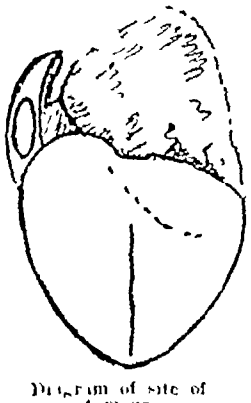

Diagram of site of tumour.

Microscopic

Cyst Wall.—The sections show that the wall consists of hyaline fibrous tissue in which are interstitial spaces, *mainly small and containing* isolated red blood corpuscles. In other parts *larger spaces resembling cholesterol* clefts are seen with foreign body giant cells in this region. A further feature is a considerable amount of apparent blood pigment, golden brown in colour, lying free in places and in others within the cytoplasm of typical and atypical epithelial cells of a *squamous type. The inner part of* the wall is non-cellular and homogeneous. There is a moderate amount of leucocytic infiltration, *mainly of the round-celled type.*

Intracystic Growths.—The sections of the solid intracystic growths show what might well be termed an angio-endothelioma, the bulk of the growth being composed of endothelial cell with a tendency in parts to an alveolar arrangement. The blood spaces are numerous, varying in size, some showing a flattened single endothelial cell lining others no lining cells. Red blood corpuscles are present in most spaces, with occasional leucocyte. The first impression of the microscopic section suggested a similar picture to that seen in a 'mixed' tumour, but the section examined show a *uniform appearance*, which I have termed an angio-endothelioma.

Mixed-cell tumours are of comparatively common frequency in the oro-facial region, where they are grouped around the upper alimentary and respiratory tracts. The usual situation of such tumours is in the salivary glands, but they are found also in the palate, lip, orbit, molar glands, and, very rarely, in the nasopharynx,[1] nasal fossa,[2] and, as recently described, growing from the posterior aspect of the thyroid cartilage.[3]

The situation where these neoplasms are found next in order of frequency to the salivary glands is in the palate. In the latter location, however, they are regarded as *rare* tumours. Eggers,[4] in 1928, reported that there were published accounts to be found in the literature of over one hundred mixed-cell tumours of the palate, but only about one-third of these had occurred in the *soft* palate. Sonnenschein,[5] in a more recent contribution, states that the number of mixed-cell tumours of the soft palate recorded up to date (1930) is under fifty, and he describes two personal cases. Stuigis[6] in tabulating a series of fourteen cases of mixed-cell tumour of the soft palate, states that these tumours usually occur on one or the other side of the soft palate, and very rarely in the mid-line. The most important clinical facts connected with mixed-cell tumours are their *long duration, slow development*, and absence of metastases, malignancy of such palatal neoplasms is much rarer than that of similar growths *occurring* in the salivary glands. Stuigis is of the opinion that the duration of the tumour depends on the susceptibility of the patient to one or more of the following factors in order of frequency: (1) interference with phonation, (2) interference with deglutition, (3) interference with respiration.

In the case reported above the tumour had been present in the left side of the soft palate for at least fourteen years, and there was no clinical evidence of any metastases. Probably owing to the very slow growth of the tumour the patient became accustomed to the gradual diminution of the air and swallowing space and he made no complaint of dysphagia, and could eat ordinary food until the "lump had been needled." His speech was altered, but respiration was unaffected.

Histologically the neoplasm described consists of epithelial cells, *endothelial cells, and blood spaces.* Fry,[7] in his account of mixed salivary tumours, describes one type of mixed-cell tumour in which the cells are abundant, are closely packed in irregular masses without any definite arrangement, and in which it is impossible to demonstrate any stroma. Eggers also, in his histologic analysis of four cases of mixed-cell tumour of the soft palate, reports that they consisted mostly of dense masses of epithelial cells, *cartilage being very rarely found.*

The majority of mixed-cell tumours are characterized by a scanty blood supply, the vessels being few in number and very thin-walled, often consisting merely of an endothelial lining. Nevertheless authentic examples of mixed cell tumours have been described in which *there has been* an abundant vascular network.

Eggers describes a tumour (Case III) which "consisted almost wholly of *massed* epithelial cells, within the masses were cavities lined by flattened cells, cartilage or squamous epithelium were not found." Fry also records a *case of* a tumour entirely encapsulated, a large part of which consisted of a solid mass of cells of irregular shape, with no definite arrangement, a prominent feature was *its* extreme vascularity.

Small cysts due to degenerative changes are of frequent occurrence in mixed salivary tumours, and it is probable that in the case recorded above there had been a periodical ooze of blood from such an extremely vascular tumour into a small cyst, thereby increasing its size, and giving rise to the straw-coloured fluid contents and the deposit of blood pigment.

The above features lead the writer to conclude that the tumour was a mixed-cell tumour of the soft palate with an exceptionally abundant blood supply and containing a cyst of unusual size

No attempt is made to discuss the etiology of this tumour as there are numerous and excellent contributions by many authors available for consultation and as McFarland says "Whenever in the face of these excellent contributions undertakes to add to the literature might well be called upon to apologize"

DELAYED OPERATION FOR TRAUMATIC INTRA CEREBRAL HAEMORRHAGE

BY

D. K. SABHESAN, M.S., L.R.C.P. AND S.,

CIVIL ASSISTANT SURGEON, GOVERNMENT HOSPITAL, GUDIYATTAM

(*With Special Plate*)

THE mortality after operations for traumatic intra-cerebral haemorrhage is sufficiently high that it may be worth while considering whether delayed operation is more likely to be beneficial in such cases

The following particulars of a case of head injury I recently operated on will, I think, be of general interest During a quarrel a man, aged 30, received a blow on the left side of the head with a bamboo stick, at about 7 P.M. on April 20th, 1930 He was brought to the hospital at 8.30 o'clock the following morning in an unconscious state He had a large contusion over the left side of the forehead involving the eyebrows, eyelid, and the temple Both pupils were contracted and equal and there was no haemorrhage or cerebro-spinal fluid from the ear, nose, or mouth His pulse was 62, small in volume, respirations 20 and shallow, and he was having involuntary micturition and defaecation He remained in this state till April 24th, when he recovered consciousness but was unable to speak, and was completely paralysed on the right side (face and limbs) He was still having involuntary micturition and defaecation His pulse was 68, respirations 18, pupils both reacting to light but left a little sluggish, and deep reflexes completely abolished on the right side He was advised an operation which he refused He continued to be in the same state, and in spite of careful nursing he developed a small bedsore over the sacrum On May 6th he started getting evening rise of temperature, and he was complaining of persistent headache On May 17th he consented to be operated on When under chloroform a U-shaped flap with apex upwards was turned down from the temporal region, a longitudinal fissured fracture, running from the supraorbital margin upwards, backwards, and outwards across the frontal and parietal bones as far as the parieto-squamous suture was seen The skull was trephined over the middle of this and a disc of bone removed The anterior branch of the middle meningeal artery was exposed under the trephine circle and was found not to be damaged There was a little oozing of dark venous blood from the anterior edge of this opening, and the circle was enlarged in this direction, the underlying surface being digitally explored a few clots were expressed from the antero-inferior angle of this opening As there was not sufficient evidence of extradural pressure to account for his symptoms the opening was further enlarged towards the postero-superior angle and the underlying surface explored with the finger There was no evidence of accumulated blood-clot in this area The dura was then opened by a crucial incision (after ligating the middle meningeal artery as it was in the way) and the cortex was exposed The surface was dull and bulging through the opening in the dura A closed pair of artery forceps was thrust into the substance of the brain in the direction of the pre-central convolution and on opening the blades a large quantity of altered blood-clot and degenerated and softened brain matter was evacuated The cavity was subsequently irrigated with saline and at this stage the brain regained its colour and began to pulsate The dura was then stitched up, and the wound was closed with a sterile gauze drain He was put on regular doses of bromides His temperature came down to normal the next day and when the gauze drain was removed a little pus-stained fluid was evacuated On May 22nd slight finger-movements were noticed on the right hand His limbs were now supported on splints, the shoulder being kept abducted and the wrist dorsiflexed On May 25th slight movements of the right leg were noticed Sutures were removed on this day and the wound was found to have healed by first intention The patient by now had gained control over micturition and defaecation and he was given daily massage to his paralysed limbs, morning and evening On May 30th he spoke a few words On June 8th he could walk with the help of a stick, although with jerks Movements at his ankle could move the fingers of his hand slightly and was able to speak a few words but he was absolutely unable to move his forearm or hand independent of support On June 12th he was able to move his wrist and elbow, but his power was still very weak On June 14th he was able to flex his elbow-joint voluntarily and when the arm was raised up and supported his efforts to raise the arm above the level of the shoulder were noticed by slight contractions of the deltoid and spinati On June 20th he was discharged from hospital when he was able to walk well and speak though slowly and with deliberation He had completely recovered function in his lower limbs, and was able to use his upper limb with a slight weakness of the abductors and external rotator of the upper arm and with inability to approximate his little and ring fingers On August 1st he appeared in court and argued his own case His movements in the shoulder-joint are still restricted and weak There is slight wasting of the muscles of the hypothenar eminence and inability to oppose his ring and little fingers completely His speech is slow and there is a little hesitation in it

The photograph reproduced in the Plate shows the state of operation and demonstrates the patient's ability to raise the arm to the level of the shoulder, and also shows his inability to approximate the little and ring finger

Memoranda.

MEDICAL, SURGICAL, OBSTETRICAL

AN UNUSUAL CASE OF STIFF KNEE

(*With Special Plate*)

THE following case appears to be a unique example of stiff knee and there is so far as I am aware no record of a similar case in the literature of the subject The rarity of the condition places it in the category of a museum specimen rather than in the more valuable and more useful sphere of everyday work Nevertheless it is worthy of being put on record and therefore I venture to publish it as a radiological contribution to the study of stiff knee

Rather less than a year ago I was asked to make an x-ray examination of a left knee-joint which had become practically immobile in a slightly flexed position and by the courtesy of the patient's doctor I was able to obtain the following history

Mr. H., aged 53, stated that the early stiffening of the joint in her left knee was experienced about the beginning of the year 1926 and took the form of a stiffness rather than of pain Up to March 1927 she was able to walk quite well with a stick and flex her knee without any great discomfort and range of flexion at the knee-joint In March 1927 she underwent an operation for internal cartilage and [illegible] that she was able to walk into the operating theatre in quite a normal manner but on awakening up in bed from the anæsthetic she experienced an acute pain in the knee This was the first occasion on which really acute pain had occurred She remained

in hospital about a month and the knee did not improve At this time it was still possible to flex and extend the joint passively, but active movement could not be carried out The condition of the knee was considered to be due to rheumatism, and was treated accordingly

When she left the hospital she was unable to walk Some months later her leg was put into a long splint, and was kept thus for a period of about seven weeks, with the knee joint extended When this splint was taken off, another one was applied with a foot piece, and kept on for 'weeks and weeks" When the second splint was removed she lay in bed for months, and was afraid to move her knee on account of pain About April, 1928, the knee was x rayed at another hospital, but apparently nothing definite was discovered However, a diagnosis of rheumatoid arthritis was made It appears that only an antero posterior and a postero anterior view of both knees had been taken For a month or two before I x rayed the knee, on November 28th, 1929, she had been able to walk about a little without experiencing much pain

Clinically the knee presented no abnormal appearance, but any attempt to extend or to flex it further was frustrated by reason of its rigidity and on account of the discomfort caused to the patient A slight degree of lateral movement could be obtained by placing a hand on each side of the knee while the foot was held between the manipulator's knees (This movement can be obtained in a normal knee when the limb is slightly flexed and the thigh muscles relaxed) A small amount of rotation could be produced by grasping the thigh just above the knee with one hand and rotating the tibia by gripping the ankle with the other These movements, though limited in extent, indicated that no osseous ankylosis was present, and, as there was no marked evidence of contracture of the muscles, it was difficult to imagine what factor or factors could be held responsible for the stiffness of the joint It was on these grounds that the masseur who had been engaged to attend to the patient decided to ask for an x ray examination before proceeding in his endeavour to loosen the joint by manipulations Fortunately for the patient she had been placed in the hands of a competent masseur of the modern school, whose training included an adequate knowledge of anatomy, physiology, and some pathology, as well as the methods of manipulation, she was thus spared forcible measures, which would have caused great subsequent pain without improving the movement of the joint, and which possibly might have been productive of considerable damage to it

The radiograph revealed a condition which gave rise to great astonishment Proceeding from the anterior surface of the external condyle of the femur a large sessile cone-shaped exostosis was seen, which had invaded almost the whole depth of the patella The patella was, in fact, transfixed, and it was now easy to understand why the knee-joint was incapable of flexion and extension The quadriceps could no longer pull the patella upwards, and flexion could only have been obtained by forcibly stretching the ligamentum patellae

As it was a stereoscopic radiograph that had been taken, it was possible to say definitely from which condyle the exostosis arose, and it was also possible to see that the exostosis had actually entered the patella

I made prints from two diapositives of the radiograph, one to show the actual size of the parts (Fig 1) and the other to show the relationship of the bones (Fig 2) In preparing the diapositives I have been able by carefully grading the light transmitted through the x-ray film to produce diapositives from which bromide prints have been obtained, which show up the details of the exostosis and the patella without sacrificing the visibility of the details of the rest of the joint

At the present time (September, 1930) clinical examination reveals no difference in the appearance of both knees The left one measures 18 inches in circumference as against 17 inches in the right The left calf measures 17½ inches, and the right 17 inches The patient walks with fair comfort, but in an attempt to make up for the shortening due to the slight flexion of the knee she is developing a talipes equinus, as the heel is raised up and the tendo Achillis is becoming retracted

There is no doubt that there is some degree of contracture of the flexor muscles otherwise it should be possible to extend the joint passively, as the fixed patella would scarcely prevent that Since she is unable actively to flex or extend the joint, it appears that contracture of the flexor muscles is the cause of the slightly flexed position now assumed by the joint, and I think it is evident that the ultimate degree of flexion will depend on the extent to which the ligamentum patellae is able to resist being stretched

I desire to express my indebtedness to Dr D R Reid of Milngavie, the patient's present doctor, and to Mr Thomas Kerr, the masseur But for the acumen and assistance of these two gentlemen this interesting case would probably have gone unrecorded to the limbo of lost cases

SUICIDE IN POST-ENCEPHALITIS EPIDEMICA

WHILE it is recognized that suicide is liable to take place in encephalitis epidemica, examples are fortunately uncommon P K McCowan indicated, in the *Lancet* in 1925, that "suicide is regarded as an extremely rare occurrence in epidemic encephalitis" He described in his article, however, three cases showing sequels of encephalitis in which attempted suicide was a feature of the psychosis Frederick Roques has quoted a series of cases investigated by Professor A J Hall Two of these patients threatened suicide, and a third made two unsuccessful attempts on her life The case I here record was the last of a group of six or seven which were diagnosed in the district

Mrs H , aged 27, had an acute attack of encephalitis epidemica in March, 1924 The initial phase of her illness lasted for about five weeks Diplopia, headache, lethargy, vomiting, and delirium were prominently marked About a year afterwards the use of her left arm was impaired, and spasticity slowly advanced A few months after her marriage in 1926 she gave birth to a healthy child, and sixteen months later a second well developed baby was born Both children have maintained their good health. Paralysis agitans appeared in the left hand, but the patient was capable of doing some housework Salivation was extreme, and speech was slurring Although her mental activity was slow there was no history of delusions or hallucinations Depression was unusual The post-encephalitic stage was aggravated at each pregnancy Seven months ago the typical Parkinsonian syndrome developed There was mask like immobility of the facies and stiffness of the limbs She committed suicide on July 7th by drinking a quantity of some disinfectant fluid

The special interest of this case lies in suicide occurring in advanced Parkinsonism where there had been no earlier manifestations of great mental disturbance

My thanks are due to Dr V N Harcourt for the details of the original attack of epidemic encephalitis

RAYNAUD'S DISEASE

A LADY, aged 45, came to me early in August with all her fingers and her thumbs of a waxy pallor, swollen, and very painful A gangrenous patch was present at the end of the middle finger of the right hand, at the bottom of which bone could be felt There were also small sores on the ends of all the other fingers except the little ones She had very little power of movement of any of the finger-joints There was the same waxy pallor and pain in the front half of both feet, but no sores Her blood pressure was low, 120 mm , and the artery at the wrist soft It was a typical case of Raynaud's disease

I ordered her parathyroid (P , D and Co) 1/10 grain first thing in the morning on an empty stomach an hour and a half before breakfast, and 15 grains of calcium lactate with 7 minims of tincture of digitalis three times a day after meals

Pain in the hands ceased after a fortnight, and the small sores at the ends of the fingers had healed The swelling was also subsiding in the hands and feet, and the gangrenous patch was looking much more healthy An ichthyol and zinc ointment was used for this After five weeks the hands and feet were of a normal pink colour, the swelling had all gone, except in the right middle finger, and the patch had filled up and was covered with healthy granulations Movements of the finger-joints were free, except for some stiffness in the terminal ones After two months' treatment the gangrenous patch had completely healed

The important part of the treatment has I believe been in giving the parathyroid on an empty stomach well away from food In other cases, such as psoriasis I have found parathyroid quite useless if given after meals, but very effective if given on an empty stomach

GLANDULAR FEVER

THE following case is illustrative of the recent epidemic of glandular fever and shows many departures from the typical textbook case

A very fat girl aged 16 years came under my care on April 5th When I saw her for the first time her symptoms were as follows temperature was 103 4° F there were red pimples plaque varying in size up to a shilling on the right side of the face neck and shoulder the tongue was coated the pulse rapid and the skin was dry A week's history of illness was given During the period she appeared to have had some constipation slight cough headache and nose bleeding There had been some abdominal pain but this was not very definite On examination there was an entire absence of physical signs except some doubtful rigidity of the right half of the abdomen A tentative diagnosis of an illness of the typhoid group was made and the temperature fell slowly within the next four days to 99 Coincident with the fall a few rose spots appeared on the abdomen The original plaques also disappeared about this time A Widal reaction was negative and the stool and urine showed no typhoid bacilli From now the temperature fluctuated between 98° and 99 5° for a fortnight during which the patient complained only of debility The pulse was very rapid but it fluctuated considerably with excitement About this time he was also seen by Dr Stewart of the Hendon Health Department and Dr Mack of Highbury who agreed with the diagnosis of a mild enteric attack At this period in the illness a swelling appeared in the right posterior triangle of the neck of the size of a walnut tender freely movable and non-fluctuating This subsided under fomentation but was soon followed by a similar though smaller lump under the left sterno-mastoid On April 30th the temperature rose suddenly to 103° accompanied by pain at the right base but with no cough Examination revealed impaired note and fine crepitation Respiration were now increased Thus new condition subsided only to reappear ten days later with increased pyrexia Seen by Dr C M Wilson a diagnosis of glandular fever was made and this was borne out by a blood count which showed a leucocytosis of 12 000 In the second week of May since the pyrexia had not yet subsided it was decided to give six injections of S U P An injection daily was followed by rapid disappearance of all symptoms and on May 20th the patient was apparently quite well The spleen was never palpable and the liver was not enlarged

Although the patient was feeling ill she never lost her appetite and it was difficult to believe when the temperature subsided that she had had a protracted febrile illness The points of interest in this case are the similarity to enteric infection the absence of severe symptoms, the possible effect of S U P and the congestion at the right base with pleuritic pain but no cough The cases that have been reported conform more or less to the above type and are different from those described in the modern textbook, where prominence is given to the following characteristics transitory and mild fever general and early glandular enlargement, absence of rashes and rarity of complications

DUST AND INFECTION

AT a meeting on October 21st of the Section of Pathology of the Royal Society of Medicine, Professor E H KETTLE delivered his presidential address, taking for his subject the relation of dust to infection

Professor Kettle said that the pneumonoconioses had received less attention than they deserved, for they played an important part in the life of mining populations The disease in its most concentrated form was best seen in South Africa where in the last twenty years £12 000 000 had been paid in compensation to silicotics and their widows and children Since 1911 ten select committees of legislature and five commissions had considered the matter and nine Miners Phthisis Acts had passed through Parliament The would-be miner now had to undergo a rigorous medical examination none but picked men were accepted for employment, and these were subjected to medical examinations at regular intervals

The Position in Great Britain

In Great Britain, excluding coal miners 35,000 workers were employed in the refractories industry tin mining the pottery industry metal grinding sandstone working sand blasting and other trades in which dust was a prominent feature In these scattered industries it was difficult to arrive at comprehensive morbidity and mortality figures It had been common knowledge for many years that these trades were dangerous but the first scheme of compensation for silicosis only came into operation in 1919 There could be no doubt that the industrial pulmonary disease would bulk much more largely in our social and medical legislation in the near future In these different occupations the composition of the dust would vary but all dangerous dusts contained free silica the dioxide of silicon the degree of harmfulness of a dust depended on the amount of free silica in it Although the pulmonary disability induced by the different dusts had various names such as "miners phthisis" and potters asthma the terminal pathological condition was always the same death ensued from advanced pulmonary tuberculosis Dust alone had produced disability and death in the past but under modern industrial conditions dust disease really spelt tuberculosis Pathologists were therefore required to decide, first, how silica affected the lung and how its action might be prevented or modified, and secondly how it influenced the development of pulmonary tuberculosis

Action of Silica on the Lung

The characteristic feature of pulmonary silicosis was the presence in the lung substance of isolated nodules of fibrous tissue varying in size number, and distribution Massive fibrosis was rarely seen nowadays and usually tuberculosis supervened as a frank or modified infection Until recently it was generally held that silicosis owed its harmful properties to its physical characters, the hard sharp particles were supposed to damage the pulmonary tissue For some years now however the view that silica became soluble in the tissues and that its action was chemical rather than physical had become generally accepted It was also generally accepted that dust inhaled into the terminal alveoli underwent phagocytosis by the pulmonary macrophages and was transported to various parts of the lung Presumably the silica gradually became dissolved and in its soluble state was able to stimulate the growth of fibrous tissue It was probable that fibrosis could only occur if silica was brought into direct contact with fibrous tissue or with cells capable of forming it Experimental investigations had for the most part done little to elucidate the process L V Cardner had exposed animals to dusty atmosphere for eight hours a day over periods of two to three years and had obtained important results but other workers had not produced anything comparable with what occurred in man Silica in harmful dusts was always associated with other substances and the way in which these adulterant dusts might modify the main process could only be studied experimentally Statistics were misleading it had been stated that there was no silicosis in the mines of Cripple Creek U S A and it had been thought that adulterant dusts in that region prevented the accumulation of silica in the lungs As a matter of fact it had emerged at the recent International Silicosis Conference that there was plenty of silicosis at Cripple Creek Again since the incidence of tuberculosis in coal miners was actually less than that in the general population it had been held that no silicosis occurred among them and it had been assumed that coal dust removed silica from the lung But it was now known that silicosis did occur among coal miners if the relative immunity of coal miners to

tuberculosis really existed, could it be because carbon was antagonistic to the tubercle bacillus? Professor Kettle said he had been unable to demonstrate any difference from the *normal in their reaction to the tubercle bacillus* in the case of animals saturated with carbon in attempts to block the reticulo-endothelial system. Dr. J. S. Haldane had considered that the elimination of dust particles by the phagocytes could be stimulated by non-crystalline dusts such as carbon, but experiments by Carleton and Mavrogordato did not really answer the question, and provided no evidence that coal either helped or hindered the action of silica.

Experiments by Intratracheal Injection

During the past year Professor Kettle, working in conjunction with Dr. Hilton, had introduced suspensions of dust directly into the lungs of rabbits and guinea-pigs by way of the trachea. So far they had not been able to produce the typical fibrosis, and since an adequate quantity of dust must have been introduced into the lung it was clear that the time factor was of the first importance. *Great stress had been laid on the immobilization of phagocytes* by silica, but in their experiments there appeared to be no difference between the initial reaction and the subsequent behaviour of the phagocytes when carbon was used instead of mine dust. In variations of these experiments, using mixtures of amorphous silica and carbon, and mine dust and carbon, no sign was seen of the characteristic cleansing which had been described. Coal dust was the adulterant dust most often quoted, but the speaker had no reason to believe that other dusts played any specific part in protecting the individual from the effects of inhaled silica. The base-line for experiments on this point must be the production of characteristic silicosis in animals. It was possible that adulterant dusts might actually assist the action of silica in some cases. In one factory in which an abrasive powder, consisting of 75 per cent. of silica and 25 per cent. of sodium carbonate and powdered soap, was prepared, several cases of acute silicosis had been described following comparatively brief exposure to the dust. It was known that silica was soluble in alkaline solutions, and the explanation given for the rapid onset of the disease was that the inhaled alkali increased the solubility of the silica and enabled it to act more rapidly than usual. Professor Kettle had had the privilege of examining portions of the lung in two of the fatal cases occurring in this factory, and had found advanced tuberculosis in both, he regarded this as the basis of the whole condition, though it was more than likely that the infection was enhanced by the inhaled silica.

The Effect of Silica on Pulmonary Tuberculosis

Nowadays industrial workers were seldom "choked," as it were, with dust, but they inhaled a certain amount of silica, which *might produce a fairly advanced fibrosis* of the lung. The chief danger, however, lay in the influence dust exercised on microbic infection, and especially on the tubercle bacillus. It was formerly supposed that it was the fibrosis induced by the silica which in some way predisposed the lung to tuberculosis, presumably from interference with lymphatic drainage. No experiments had been carried out in this country on the infection of the fibrotic lung, but fairly extensive observations had been made on the effects exercised by silica on tuberculosis in laboratory animals. Some years ago, working with W. J. Cye, Professor Kettle had demonstrated that interstitial inoculation of different forms of silica produced characteristic necrotic lesions, and that tubercle bacilli proliferated readily in these lesions in such unsusceptible animals as mice. Later he had been able to show that the active growth of bacilli did not depend merely on the necrosis of tissue, but was due to the actual presence of silica, and further experiments had confirmed this view. He did not wish to lay too much stress on his experiments, but they all pointed in the same direction, and he thought they were significant. In another series of experiments carried out with Dr. Hilton he had given intratracheal injections of silica to rabbits and guinea-pigs, and some weeks later had inoculated them intratracheally with living tubercle bacilli, arranging for an adequate number of controls. All the animals had died with pulmonary tuberculosis, but the silica animals had died weeks, or even months, before the controls. These experiments were also suggestive, but he was *not prepared to say more than that*. L. V. Gardner, however, had performed an experiment which appeared to him to be crucial. At Saranac there was a strain of tubercle bacilli ("R 1") which produced in guinea-pigs infected by inhalation, isolated subpleural nodules in the lung, and massive involvement of the tracheo-bronchial glands. Macroscopic tubercles in other viscera practically never occurred. Resolution and healing ensued in eighteen months to two years, and the infection was practically never fatal. Animals inoculated with this bacillus were dusted with quartz for eight hours a day over a period of two to three years. After three to five months the bacilli in the pulmonary lesions took on a new capacity for growth, massive ulceration occurred in the lung, and the infection spread to the abdomen. This change was not attributable to an exaltation of the virulence of the bacilli, for subinoculations from the animals produced merely the form of tuberculosis characteristic of the "R 1" strain. It appeared to be due to an alteration of environment, depending on the presence of silica. How silica acted was still doubtful. Cummins had suggested that it destroyed complement, but to Professor Kettle the phenomenon appeared to be a cellular rather than a humoral one. Either the intracellular defensive mechanism of the phagocyte was injured by the silica, or the nutritional value of the cell protoplasm for the bacillus was enhanced. Working with cultures *in vitro* he had found that, although the total growth of the bacillus was unaffected, the lag period seemed to be shortened, so that an abundant growth was obtained in a much shorter time when silica was added to the medium. The experiments, however, were irregular, and so far he was not prepared to say that any success he had had was more that accidental. As regards the *in vivo* investigations, he did not think there could be any doubt about the main facts, although the explanation was still unknown.

Infective Silicosis

In South Africa a simple silicosis and a silicosis with tuberculosis, or tuberculo-silicosis, were recognized. In addition, they described another condition—infective silicosis—in which infection was believed to produce changes in the reaction of the tissues to dust. The nature of the infection had not been determined in every case, but the tubercle bacillus was thought to be the most important organism. Radiographic examinations revealed larger and more irregular nodules of fibrosis than those found in typical simple silicosis, and on microscopical examination there appeared to be a greater tendency to necrosis. The lesions showed no histological evidence of tuberculosis, even when the nodules developed as the result of the combined action of the bacillus and the dust, but nodules from these cases inoculated into guinea-pigs gave rise to tuberculosis, although the bacillus appeared to be of an attenuated type. The opinion of South African workers at the recent conference was that silica might actually damage the bacillus so as to lower its virulence. It was difficult to reconcile this view with experimental data, which all went to show that the influence of silica was always favourable to the bacillus, but Professor Kettle felt that the experience of South African workers was so great that considerable weight must be given to their views.

RESEARCH IN CLINICAL MEDICINE

At a meeting of the Section of Medicine of the Royal Society of Medicine, on October 28th, with Dr. R. A. Young in the chair, a discussion on research in clinical medicine was opened by Dr. J. A. Ryle.

Dr. Ryle said there was a prevailing *dissatisfaction* in this country with achievements in clinical medicine and the conditions on which they depended. The extension of laboratory tests had led to an uncritical attitude in diagnosis, while prognosis had not advanced greatly owing to neglect of the study of the natural course of disease. A reawakening of the philosophical attitude in medicine was needed. In a paper in the *British Medical Journal*

(March 15th p 479) Sir Thomas Lewis had pointed out that the work of the great clinicians was carried out upon actual sick persons Research in clinical medicine should depend on the study of the behaviourism of man in disease The method might be observational or experimental Harvey and Darwin had used both methods Clinical scientists had realized the value of coupling the two but the developments of pathology and physiology had led to a division of labour The busy life of the clinician left him little time for experiment Both Sir Thomas Lewis and Mr Wilfred Trotter[1] in their papers on this subject had seemed to imply that the observational method was at an end, but this was not the case There were now better opportunities than ever before for accurate observation the use of instruments of precision, such as the stethoscope and the electrocardiograph was not an extension of the experimental method Radiology and biochemistry merely offered improved means of observation But the trial of new drugs and the invention of a new operation were experimental methods of research The modern trend was the study of the personal, vital, and genetic factors, and the idiosyncrasies of man to disease The older physicians had studied the phenomena of disease and had made comparison with the findings in the cadaver they had also paid superficial attention to temperament heredity, and environment They were limited by their ignorance of physiology, and by the absence of accurate methods of observation A more minute analysis of morbid phenomena was now possible, but symptomatology was still largely unexplored, more accurate observation was required to determine the cause of nausea heartburn and vague abdominal pain leading to fruitless operation In therapeutics the value of vaccines and endocrine therapy still required assessment Psychology was a science founded on observation alone, and neurology had advanced by science and surgical experiment At present as Sir Thomas Lewis had pointed out, there was no adequate provision or encouragement for any young man to undertake research He was seldom in a position to devote his entire time to it, and general practice left little leisure or energy for other pursuits A research grant gave no security for the future No one could study patients other than his own, but while so engaged a man should be relieved of financial anxiety Sir Thomas Lewis had suggested that young men without experience of general practice should be encouraged to undertake research, but in the speaker's opinion it should be allocated to men who had practised he would like to see a post created at the general hospitals for a man having access to all the patients in the wards and with a few beds of his own The appointment should be for five years, and be either renewable or leading to a post on the staff A man with a wide early experience, and preferably with a grounding in philosophy and psychology should be chosen The Medical Research Council was prepared it seemed, to help to solve the problem

Professor H Moore of the University of Dublin remarked that, until recent times clinical research had depended on bedside observations and simple tests, which were correlated with post-mortem findings Later, clinicians had come to think of disease in terms of physiology—that is, in terms of the living organism more precise methods involving laboratory technique and the use of experimental animals were introduced, and training in the interpretation of results became necessary to the physician As knowledge progressed problems could no longer be settled by observation alone and the laboratory became a necessary adjunct the physician was the person to pursue the study of disease provided he had access to both the patient and the laboratory Acidosis, ketosis, and diabetic coma were conditions which had been elucidated by combining the work of laboratory and clinic The discovery of insulin and of the liver treatment of anaemia were the work of the laboratory but their value was tested and proved in the clinic The majority of advances made in recent years had depended on the collaboration of the clinic and the laboratory Research was most productive when it was carried out on the patient by men competent to use both clinical and laboratory methods, and where the clinic and the laboratory formed one synergic unit The simple mode of approach was no longer effective because of the increasing complexity of medicine If funds were available to build new hospitals he would suggest that buildings should be constructed for the following purposes first, the care of the sick secondly the study of disease in the patient by the co-ordination of all possible means thirdly the instruction of students research workers and nurses and, finally, for the after-care and after-study of the sick Whether a research worker should hold a whole-time or a part-time appointment was a matter for debate There was much to be said for giving a man a reasonable tenure of a whole-time post with obligation to deliver a few lectures and arrange demonstrations in his own subject, provided he had facilities for keeping his view wide and general The purpose of medicine was to cure disease, and a man should not be allowed to make the means the end by devoting himself entirely to the scientific aspect Those general practitioners who wished to pursue a definite line of research should also have opportunity to do so The training of a research worker should include clinical and laboratory experience He might begin with simple research under supervision doing his own laboratory work and using animals later he would be competent to advise on complex research A body to organize and allocate research would be valuable Appointments might be for a period of five years, and would in any case enhance the ability of the worker to diagnose and treat disease Wherever possible a research unit should be organized in hospital where the clinic and the laboratory might work in close co-operation

Dr Helen M Mackay said there was no lack of ability among clinical research workers in the country but there was an absence of facilities we were advancing slowly but undoubtedly there was much talent awaiting better opportunities The needs of the clinical research worker were adequate material, assistance and sympathy from his fellows and time—with the inevitable corollary of money—for thought, reading and correlation of facts Material was best investigated in institutions for the general practitioner controlled work was almost impossible The worker must have experience and standing sufficient to make him a suitable person to hold a post with beds allocated to him The voluntary hospitals had done little in the past to further clinical research and even looked unfavourably on a man who pressed for improvements in equipment and apparatus The sympathy and assistance of colleagues, alone was not enough a research worker should have the support of the nursing and managing staff of the hospital The lay public not realizing the importance of research were inclined to put obstacles in its way much could be done by the press to educate public opinion on this point The demands made by research on time and energy rendered few ready to undertake it at a disproportionately small income The leisure of a young man was small and whether he aimed at consultant or general practice all thought of research must be eliminated A few scholarships were obtainable at £50 per annum for half time and £350 for full time service and these were only given to men or women with post-graduate experience, many of whom had held a university lectureship This should be contrasted with the minimum of £600 a year which had been laid down for the public health service Moreover there was no security at the end of the appointment As in other fields the first work done was seldom the best and workers required opportunity for experience In Austria research was an integral part of every university hospital conducted by a full-time staff In a town the size of Reading research of a high order was being conducted at a kinder klinik equipped with excellent facilities including opportunities for animal experiment in the same building In the speaker's opinion clinical research workers should receive an initial scholarship to determine their suitability but some permanency of tenure should be offered and there should be hope of ultimate advancement Whether the post was a full- or part-time one might depend on the conditions under which the candidate produced the best work Where the value of research was appreciated such a scheme might become a reality

[1] *British Medical Journal*, July 26th, 1930 p. 129

Dr F Parkes Weber thought that until the medical profession in England set the example in research they had no right to call on the lay public for large donations He advised the production of fewer textbooks on general medicine and the publication of more monographs, which would encourage research He also advocated the organization of a library of pathological slides for the use of those who wished to make comparison of sections of disease taken from their patients Dr C M Wilson was strongly in favour of an extension of the unit system to clinical research It was a mistake to regard the laboratory and clinic as divorced from one another So long as an accurate answer could be given it mattered little where that answer was obtained Dr A Eidinow put in a plea for the man who wished to do original research Much work grouped under the heading of research was pure scientific investigation—such as the standardization of drugs—carried on by men who, whatever their training, were scientists, and not medical men at heart He asked that some scheme might be devised to encourage the man who wished to do original medical research

Dr L Findlay doubted whether the suggestions made by any of the speakers would have any effect Every new invention opened a new field of research, and there was plenty to see if there were the men to see it Research workers were born, not made, and genius flourished in adversity No man was *entitled to be put in the lap* of luxury simply because he could perform accurate tests Dr C W Theobald thought it was ridiculous to expect British research workers to hold their own while the present system obtained By the time a man had an opportunity for research he had lost the taste for it A fundamental change was needed Dr J Kingston Barton said that the object of medicine was to treat disease, it was impossible for a man to devote himself to clinical research to the exclusion of the practice of medicine Dr W R F Collins remarked that the clinical researcher was faced with the problem of whether to go into practice or go into debt It was impossible to dissociate the clinician and the laboratory worker The clinician must have some idea of laboratory tests, but at present, if he spent half his time in the wards and half in the laboratory, he was looked at askance by his colleagues in both quarters He would prefer that the system should develop along those lines, however

In replying, Dr Mackay said she would like to see people pressing for increased facilities for research at their own hospitals Dr Moore urged that some of the funds obtained by hospital sweepstakes should be dedicated to research Dr Ralf regretted that he had found the meeting as unproductive as he had feared it would be If bacteriology, pathology, and physiology were to be endowed, clinical research should be given equal opportunities

REGULATION OF THE OVARIAN CYCLE

At a meeting of the Sheffield Medico-Chirurgical Society, held at the University on October 22nd, with the president, Professor Graham Simpson, in the chair, Dr A S Parkes, Beit Memorial Research Fellow, University College, London, read a paper on the regulation of the ovarian cycle

Dr Parkes said that various lines of work had all tended to show that the activity of the ovary was regulated from some external source It was found many years ago that the ovary of an immature animal grafted into an ovariectomized adult female immediately underwent development and began its morphological and endocrine cycle long before it would have done so in its original environment This and similar observations demonstrated quite clearly that the functional age of the ovary was regulated by that of the soma It was now well known that the number of follicles ovulating at a time was governed, not by the amount of ovarian tissue present, but by the amount available of some substance in the circulating blood Periodic action of the oestrus-producing hormone could also be demonstrated after complete elimination of the cyclic structures of the ovary by exposure to x rays The periodic mechanism, whatever it might be, was thus probably located elsewhere than in the ovary Uterine experimental work carried out during the last few years had revealed an amazing mechanism whereby substances elaborated by the anterior lobe of the pituitary body activated the ovary One of the anterior lobe substances was concerned with the maturation of the Graafian follicle and ovulation, while another was responsible for causing the formation of the corpus luteum from the shell of the ruptured follicle The "lutemizing" substance administered to an animal with a quiescent ovary caused the follicular granulosa to undergo lutemization without the intermediate act of ovulation The other substance caused the quiescent ovary to enter on a phase of follicular maturation, culminating in ovulation and the formation of the corpora lutea In each case changes were observed in the accessory organs corresponding to the phase induced in the ovary and resulting from the stimulation of ovarian endocrine activity The action of the substances was exerted solely on the ovary and thence on the accessory organs Anterior lobe preparations had no effect in the ovariectomized animal The discovery of the anterior pituitary substance had explained the nature of the stimuli responsible for evoking the different phases of ovarian morphological and endocrine activity, but little progress had been made in elucidating the means whereby the periodic activity of the anterior lobe hormones was organized Presumably some kind of endocrine cycle existed in the anterior lobe, but attempts to obtain histological evidence of this had so far been abortive In any case, whatever the cycle mechanism in the anterior lobe might be, it was necessary to suppose that it could be modified by such events in the accessory organs as pregnancy, during which prolonged luteal activity was found

The paper was discussed by the President, Professor Leathes, Professor Phillips, Dr Elizabeth Eayrs, Mr W W King, and Mr H Blacow Yates

ENURESIS

The opening meeting of the London Jewish Hospital Medical Society was held in this hospital on October 9th, when Dr Leopold Mandel delivered his presidential address on enuresis

After reviewing and discussing the various theories with regard to the etiology of this condition, he put forward a plea for closer co-operation between the practitioner, the paediatrist, the urino-genital surgeon, and the psychologist, with a view to solving a problem which he considered to be one of the most troublesome in medicine He hoped that more attention would be paid to the relationship between the vegetative nervous system and the bladder, and advanced the view that the enuretic patient was an individual whose neuro-muscular micturition mechanism was not normally stabilized Many factors which did not affect the normal child acted as adverse stimuli in the susceptible incontinent child He suggested the following classification into five groups with a view to making the types more easily recognized clinically, and enabling approved therapeutic measures to be adopted (1) Those in which some palpable physical irritating stimuli existed, such as worms, over-distension of bladder, or cystitis Their treatment was obvious (2) The hypersensitive, neuropathic, or nervy type, in which the instability was a symptom which might be regarded in the same light as other symptoms, such as cyclic vomiting, ketonuria, and vagotonia, etc., which were more commonly found in the nervy child They responded to dietetic and medicinal measures, combined with readjustment of environment and gentle re-education (3) The so-called psychopathic child, in whom the enuresis was more a behaviour complex, and the treatment required was for the most part psychological (4) Endocrine dysharmony, particularly hypothyroidism, leading to a loss of inhibition Thyroid in small doses was indicated, while pituitrin by its tonic effect on unstriped muscle, was a good adjuvant (5) The debilitated child, often convalescent from some illness General tonic treatment was indicated In all cases atropine or belladonna was the specific drug of choice, while in the management of the case patience and the closest co-operation between the doctor, the child, the parent, and the teacher were essential.

Reviews.

THE SCIENCE OF CHEMOTHERAPY

The fact that *Recent Advances in Chemotherapy*,[1] by Dr C M Findlay, is the first work published in this country dealing generally with chemotherapeutic agents and their application, may serve to indicate the scant attention British workers have paid to the development of this science Not only does the number of chemotherapeutic agents discovered in this country compare unfavourably with the number discovered in Germany or in the United States but the general ignorance about chemotherapy is so great that the term is often used as it it meant merely the study of antisyphilitic remedies It is interesting to note, therefore, that these latter substances are disposed of in less than one-fifth of the volume under review, nearly the whole of the remainder dealing with the treatment of tropical and subtropical diseases caused by animal parasites The importance of chemotherapy to our nation is obvious when it is realized that the prevalence of these diseases in the British Empire creates serious economic problems, and that the development of tropical and subtropical countries is largely dependent on their eradication or successful treatment

The introduction of organic arsenicals in the treatment of syphilis still remains the most sensational discovery made in chemotherapy, but many of the recent advances in the chemotherapy of tropical diseases, though not so sensational, have equal if not greater importance on account of the enormous number of sufferers concerned For example, so great a part of the world's population is afflicted with hookworm disease that a campaign against this infection may demand the treatment of hundreds of thousands of patients When drugs are used on such a scale any advance is important whether it is towards a reduction in toxicity or an increase in potency, or a price reduction, or a greater stability Judged by these criteria the application of carbon tetrachloride to the treatment of hookworm disease represents a very important advance for this agent seems to be better in several respects than any drug previously used Similarly, the pentavalent antimony compounds recently introduced for the treatment of kala azar are effecting a considerable saving of life Intravenous injection of tartar emetic reduced the mortality from over 90 per cent to under 20 per cent, this treatment was liable however to produce toxic sequels and the application of pentavalent antimony compounds has resulted in a further reduction of the mortality to about 4 per cent

In the treatment of malaria any advance, however small, is welcome It is unlikely that the new drug plasmoquine will replace quinine, but it is more effective than quinine in its action on the sexual forms of the malaria parasite, and may therefore prove of great value in the sterilization of malaria carriers Most significant of all is the fact that a method has been discovered by which the antimalarial action of drugs can be estimated experimentally on animals and by its means a number of antimalarial drugs have been synthesized It is reasonable to expect that in the near future drugs may be discovered having even greater potency than plasmoquine

On the whole, the chemotherapy of bacterial infections is still unsatisfactory, and in the volume under review less than one hundred pages are devoted to the subject but even here there have been a few successes particularly in the treatment of leprosy and to some extent in the treatment of tuberculosis certain cases of which respond favourably to injections of sanocrysin

Dr Findlay has produced a readable survey of a difficult subject his work is written from the medical point of view, the material being classified according to diseases, while the actual chemical detail is limited to a description of the structure of the more important products More than two-thirds of the work is devoted to the chemotherapy of protozoal infections the remainder being concerned with helminthic and bacterial infections and cancer

ORTHOPAEDIC SURGERY

Not three years have passed since we noticed in these pages the eighth edition of Whitman's *Orthopaedic Surgery*[2] and a copy of the ninth edition is now before us As the number of pages has been increased by twenty-four and the number of illustrations by twenty-seven, we may safely assume that care has been taken to keep this standard textbook up to date There have been no revolutionary or even striking innovations in orthopaedics since January 1928 and therefore it is not to be expected that any great change would be noticeable in this work Like some other books of the same kind it has its gaps For instance as we remarked the other day in a leading article on the treatment of fractured patella it contains no reference to that subject This is probably an intentional omission, as the treatment of fractures in general is deliberately excluded It is however not easy to defend this omission from a work which includes the treatment of fractures of the neck of the femur a subject which is so closely associated with the name and reputation of the author Considerations of space have no doubt carried great weight for an adequate presentation of the treatment of all fractures would involve doubling the size of the book Yet if fractures are to be treated on orthopaedic principles their treatment should be taught by orthopaedic surgeons, and Dr Royal Whitman says in his preface to this edition that 'orthopaedic surgery is concerned with bodily mechanics with the prevention and correction of deformity and with the conservation of the locomotive function"

INTERPRETATION OF DIAGNOSTIC AIDS

There is an obvious opportunity for the volume issued by our esteemed contemporary the *Lancet* and entitled *The Clinical Interpretation of Aids to Diagnosis*[3] Laboratory tests and specialized investigations are now definitely established in the scheme of medical diagnosis and everyone allows that they are often an essential part of a clinical inquiry Not a few of them require a skill in technique that can be acquired and maintained only by individual training and continuous practice Hence in these respects the practitioner has largely to rely upon the report he receives from his expert laboratory colleague This report however is necessarily in many instances a highly technical document having shades of meaning rather than a clean-cut affirmative or negative and it is written in the vocabulary created by the new developments Its full and exact significance therefore demands some skill in interpretation The ideal arrangement no doubt is for clinician and laboratory worker to discuss the whole position in consultation and if opportunity offers this is the procedure to be cultivated Unfortunately opportunity does not always offer and the practitioner is left to read the riddle as best he may It is to meet this position that the present volume has been prepared

Each of the forty-five sections included in the book is contributed by an experienced worker and the discussion is by no means a severely technical or limited one On the contrary, each topic means a short and readable chapter in which an attempt is made to show where clinical findings can be enlarged by particular tests and in what measure the results of the tests help the practical situation Not all the sections are of equal value and not all the experts will agree with all the conclusions Yet it may be fairly said that the contributors have kept well in mind the purpose of the series and that they offer substantial help to those who desire to estimate and appreciate the knowledge to be obtained from the various technical tests here discussed Few practitioners nowadays doubt values of the order Indeed the tendency is perhaps to exaggerate them and to conclude that given such and such a laboratory finding the diagnosis is concluded Readers will find no support for any such interpretation in the manual Rather they will recognize that in many instances an absolute answer is not possible and that in any event the laboratory result is a fact to be

[2] *Treatise on Orthopaedic Surgery* By Royal Whitman M.D. F.R.C.S. F.A.C.S Ninth edition thoroughly revised London H. Kimpton 1930 (9×6¼ pp xii+1025 821 figures 25s. net)

[3] *The Clinical Interpretation of Aids to Diagnosis* Vol. I London The Lancet Ltd 1930 (Demy 8vo pp viii+[illegible] 10s 6d net.)

duly weighed in relation to other facts, and not the voice of an overriding and infallible authority There are degrees and probabilities and limitations here as there are in the inquiry at the bedside The one is to aid the other, not to supersede it

We congratulate our contemporary on a scheme happily conceived and efficiently executed Two small practical points deserve a word of recognition—namely, the interleaved blank pages for personal notes and the well-written summaries that precede the several sections, these summaries (by "M H K") are indeed triumphs in the art of combining brevity with lucidity, and they serve well the purpose for which they have been constructed

THE WRONG WAY WITH MOTHERHOOD

There has recently been published a book by Miss Sylvia Pankhurst entitled *Save the Mothers*[1] It deals with the problems of maternal mortality, and to some extent with those of infantile mortality As a contribution to the scientific study of these difficult problems and to practical suggestions towards solving them the book is, however, of no value We regret to say this the more because on page after page of the volume its author manifests a strong prejudice against the British Medical Association, based upon a very minimum of knowledge It would be much pleasanter to disarm prejudice by praise if it could honestly be done The best that can be said is that the book evidences a real zeal for the reform of unsatisfactory conditions, and an indiscriminate reading of much literature on the subjects with which it is concerned The major part of the volume is made up of scattered statements culled from official and unofficial publications, of short tendencious quotations, divorced from their context, from books and articles by writers of greater or lesser importance, of brief records of maternity cases of a distressing character, some of them of considerable antiquity, and of pathetic reminiscences of the writer's childhood Even if every separate statement set down in such a fashion were itself true, the final picture presented must tend to be, and in this case is, essentially false There are, however, statements in the book which never have been, or are no longer, true, and logic is hopelessly lacking As minor, though not unimportant, illustrations of the author's methods we may take two brief, but typical, examples One hundred and ten maternity cases per annum are described as "an average of nearly three labours a week" It is stated that "The British Medical Association proposes that to provide an improved service for maternity the present national health insurance contributions should be increased by sixpence per week, the employer, the worker, and the Government each finding twopence" What the British Medical Association's scheme actually says is that "an additional contribution on behalf of the employer and worker together of 0·4d per week for each insured person, with 0·2d per week by the State, would provide all the money" An inability to do correctly a simple division sum, and a disregard for the significance of a decimal point are disqualifications for dealing with those important statistical aspects of the subject which are essential to its understanding

Miss Pankhurst gives quite a false impression of what the British Medical Association scheme provides and entails Indeed, it may be said in general that there is scarcely a single statement made throughout the book about the Association which is strictly true, and Miss Pankhurst, more in sorrow than in anger, discovers that the Medical Women's Federation is just about as bad It is not worth while to pursue this matter or to expose the mistakes, but the depths of the author's ignorance of the objects and functions of the Association may be shown by one quotation After quoting from one writer that "anyone who knowingly and unnecessarily" does certain things such as those which an entirely unrelated speaker said he had been told had occurred in a "high-class London nursing home" (with no untoward results but this Miss Pankhurst does not mention), she goes on, "One may venture to suggest that the British Medical Association might be better employed in adopting disciplinary action towards such offenders than in striking Dr Axham off its rolls for acting as anaesthetist to the famous manipulative surgeon" It ought not to be necessary to point out the distinction between the Association and the General Medical Council to a writer of whom her publisher says, "no one is better qualified than this author to present the facts" Miss Pankhurst does know of the existence of the latter body, but in the instance in which she mentions it she misstates its powers Apart from such errors and misrepresentations the illogical and inconsequential nature of the book may be seen in that the only possible conclusion from one part is that every mother ought to have her confinement in a hospital, while the conclusion from another must be that the dangers of maternity hospitals are so great that no mother ought to be allowed to submit to them

Miss Pankhurst is, however, not content to be merely contemptuous or critical of the maternity service schemes suggested by two Departmental Committees, by the British Medical Association, and by the Medical Women's Federation, she has constructive proposals of her own Their practical value can be gathered from the following features which they present Each maternity case is to be provided with a hospital bed from two weeks before the confinement till three or four weeks thereafter, and then with accommodation in a convalescent home for a further month, all this without any payment by the mother There are to be sufficient whole-time salaried and pensionable midwives and specialist medical practitioners (preferably women) to allow of each being present throughout every confinement Each midwife is to be trained for four or four and a half years free of cost to herself, and is each year, in addition to holiday, to be allowed a period for post-certification training Each birth is to carry with it a cash maternity bounty of £10 to the mother, who would, in addition, receive during the weeks of her illness an enhanced sickness cash benefit, be provided free with all the nourishment required during pregnancy and suckling and have the services of a home help, trained and paid entirely by the community If the mother be a wage earner she would also have a weekly payment equivalent to her wage when employed, for five months, or longer, before her confinement, and for one year (or, if she apply for it, for five years) thereafter Each doctor as well as each midwife would be subject to meticulous rules with regard to the conduct of their professional work, and would be subject to inspection to see that these were obeyed Need more be said? The scheme is obviously fantastic as regards expense, is directly contrary to many things which both the medical profession and the self-respecting public rightly hold dear, and would involve a disastrous and complete divorce between the medical attendance given during pregnancy and maternity and that provided during every other contingency of life

HUMAN PARASITOLOGY

Although it bears the new name *Introduction to Human Parasitology*,[2] this book by Dr A C Chandler is actually the fourth edition of his *Animal Parasites and Human Diseases* Under its old title the book was intended to appeal to a lay as well as to a professional circle of readers, but sales records showed that the general public did not greatly desire education in this subject, though the work seemed to be in demand as an elementary text book on parasitology for medical schools Much of the present work is taken verbatim from the previous edition, including some which could well have been omitted as being too popular for the circle of readers to whom the text is now addressed Many of the additions, too, could usefully have been omitted as being too specialized for an introductory course in human parasitology There seems to be no need, for example, to describe in detail parasites whose presence in man has only been reported once—and then doubtfully There are now over three

[1] *Save the Mothers* By E Sylvia Pankhurst London A Knopf 1930 (Cr 8vo, pp xiii + 216 6s)

[2] *Introduction to Human Parasitology* By Asa C Chandler, M S Ph D Fourth edition, rewritten and enlarged superseding *Animal Parasites and Human Diseases* New York J Wiley and Sons Inc London Chapman and Hall, Ltd 1930 (Med 8vo, pp xiv + 655 368 figures 25s net)

hundred illustrations, many of them good, but the efficiency of most could be increased by reducing the amount of "stippling" which in some cases is employed to such an extent as to make the figure almost unrecognizable. The work covers the protozoa (including the spirochaetes), the helminths, and the leeches as well as the parasitic and disease-carrying arthropoda. It concludes with a useful list of periodicals and standard books on these subjects. There is an adequate subject index, but several valuable pages are wasted on a list of authors—without any reference to their papers. The text is easily followed, and some chapters—particularly that on hookworms—are very good. The book still remains the most useful introduction to human parasitology in the English language, but future editions could be rendered more useful by a judicious pruning.

NOTES ON BOOKS

Of the eight main articles in the July number of the *Annals of Medical History*[1] so successfully edited by Dr. FRANCIS R. PACKARD there are four which deal with allied subjects. The history of aphrodisiacs from the earliest times to the present day is traced with copious references by Mr. H. S. Denninger of Chicago. Dr. J. L. Miller of the same city writes on the history of syphilis and arrives, in opposition to Karl Sudhoff, at the very definite opinion that there is not any evidence of the existence of syphilis in Europe, Asia, or Africa before 1493, and that there is strong presumptive evidence that it was introduced into Spain by the sailors of Christopher Columbus. Fracastorius and his poem on syphilis are described by Dr. D. W. Montgomery, who shows that this poem, which now might find difficulty in obtaining a publisher, brought affluence and European fame to its author. In his historical survey of gonorrhoea Dr. E. W. Hirsch of Chicago points out that the Jews were well acquainted with this disease, and that their prohibition of intercourse with a menstruating woman has been justified by the recent observation that the virulence of the gonococcus is then increased. The portraits of Neisser of Breslau and Ricord of Paris appear in this article, and are reproduced as the frontispiece and on the cover of this number. A very attractive and scholarly account is given by Professor A. S. Warthin, president of the American Association of the History of Medicine, of the physician in the famous *Dance of Death, which represents the fear of death in the neurotic and psychopathic Middle Ages*. Dr. Howard Jones sketches medical practice among the North American Indians when they first came in contact with white men, as is set out in Edna Kenton's work *The Indians of North America*. What Stephen Girard, mariner and merchant, did for Philadelphia in the great epidemic of yellow fever in 1793, and in subsequent smaller outbreaks, is proudly recorded by Professor Hobart Amory Hare of that city. Dr. Eugene J. Leopold of Baltimore gives an account of Aretaeus the Cappadocian and his original description of diabetes. There are a number of excellent reviews in this generously illustrated instalment.

In preparing the second edition of his textbook on *Vertebrate Embryology*[2] Professor W. SHUMWAY has thoroughly revised the text, eliminated redundant technical terms, and introduced several new diagrams. The four parts of the work are entitled respectively early embryology, organogeny, atlas of sections, and microscopic technique. The author deals with the subject by describing type embryos, choosing for this purpose the frog, chick, pig, and man. At the end of each chapter there is a useful summary and a list of works for further study.

A volume entitled *Psychoanalysis of the Total Personality*[3] is a translation into English of a monograph by Dr. FRANZ ALEXANDER based upon a series of lectures delivered at the Berlin Psychoanalytic Institute. The first part of the book represents an attempt to apply Freud's theory of the ego to the individual neuroses. More speculative are the elements contained in the second part, for here the author endeavours to further elaborate Freud's views in regard to the two classes of instinct—namely, the erotic and death instincts. Dr. A. A. Brill writes a prefatory note.

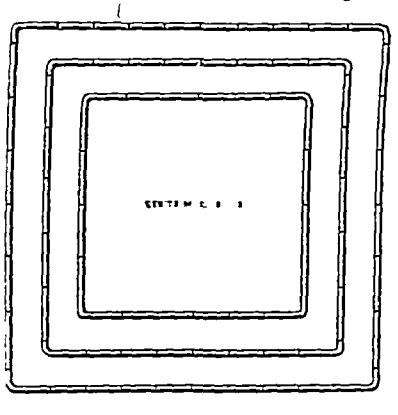
PREPARATIONS AND APPLIANCES

AN OCCLUDER FOR SQUINT

Mr. A. RUGG-GUNN, M.B., F.R.C.S. (London, W.), writes: In the design illustrated herewith the principle of complete occlusion has been dispensed with. The occluder consists of two parts: a half lens of Chavasse glass which covers rather more than the nasal half of the spectacle lens, behind which it is worn, and a rubber projection which can be trimmed where necessary to fit into the inner aspect of the orbit.

Its advantages may be summed up as follows: (1) The occluder may be said to be practically invisible. (2) It permits



central vision of the occluded eye only in the position of relaxed convergence. (3) It emphasizes the relative equality of peripheral vision in the two eyes, encouraging more reliance on the squinting eye, and thus discourages its desire for suppression and overcomes its relative immobility. (4) It encourages a position of the visual axes in which images fall on relatively corresponding points. (5) By relaxing excessive convergence it may secondarily relieve accommodative spasm.

The makers of the occluder are Messrs. Theodore Hamblin Ltd., 15, Wigmore Street, W., to whom my thanks are due for skilfully carrying out my suggestions.

RADIUM NEEDLE SPACERS

Dr. ROY WARD (Radium Institute, London) writes: The radium needle spacers as shown in the accompanying figures are of great assistance in facilitating the accurate

disposal of radium needles or seeds throughout a tumour area. Squares of various sizes—say 6, 8, or 10 cm.—are made of stout malleable silver wire and calibrated so that two opposite sides are marked off in centimetres and the other two at 1·5 cm. intervals.

The rectangular spacer is designed primarily for inserting needles or seeds at right angles to the skin surface. It will be noted that the markings on the middle limb are straddled. With these instruments a tumour area can be mapped out more quickly and more accurately than with callipers. They are both simple and inexpensive and can be obtained from the Cento-Urinary Manufacturing Company, Devonshire Street, W.1.

SMOKE ABATEMENT.

Since John Evelyn issued his protest against the "Smoke of London" in 1661 numerous attempts have been made to deal effectively with the industrial smoke of cities. In 1853 an Act was passed to regulate the emission of black smoke, and this was incorporated in the Public Health Act of 1875. A few years later a special Act was passed for London which sought to control the emission of smoke from furnaces and from steamboats on the Thames. The last Smoke Abatement Act (1926) removed the necessity for proving *black* smoke, and extended the powers of local authorities. These statutory provisions, however, have failed to achieve their object: smoke is still an intolerable nuisance. Apart from its blighting effect on public health, the annual expenditure in this country due to smoke has been estimated to be over £6,000,000.

Smoke Abatement Act, 1926, Section V

The modern way of dealing with a civic enemy is to found a society and arm it with a journal. In the third number of the *Journal of the Smoke Abatement Society*—a body constituted last year by the amalgamation of the Coal Smoke Abatement Society and the Smoke Abatement League of Great Britain—some shrewd observations are made on the legislative methods of dealing with the problem. Its main theme is the confession of the Minister of Health that Section V of the Public Health (Smoke Abatement) Act 1926 may be almost inoperable on account of the technical difficulty of framing model by-laws for the guidance of local authorities. This deadlock would seem to be worthy of Liputa.

The section referred to requires the provision in new buildings "of such arrangements for heating or cooking as are calculated to prevent or reduce the emission of smoke." No provision is made in the Act—as in the bill of 1924—to secure that the heating or cooking arrangements in new dwelling houses should also be subject to a constructional by-law. This amendment was rejected apparently on the ground that it would be inexpedient, in view of the national shortage of houses, to adopt any measure that might hinder their erection or add to their cost. Moreover, the meaning of "heating" is not precise. The official interpretation would seem to exclude the generation of heat for manufacturing purposes.

How entangled and thwarted the administration of the section must be was indicated by Mr. C. J. Allpass, vice-chairman of the Public Control Committee of the London County Council, in a paper read at a recent conference of the society. In London, he stated, a large number of new buildings are exempt from the constructional by-law made under Section 164 of the London Building Act of 1894; further, the scheme of that Act, in the opinion of the Minister, does not permit local authorities to require the submission of proposed "arrangements" or to decide upon their acceptance. Hence he concluded that the powers conferred on local authorities by Section V of the Act of 1926 are too narrow, especially in regard to the County of London, to enable really effective by-laws to be made.

Another criticism of the Act is that a statutory committee cannot be set up in London since the enabling Act of 1875 does not apply to it. While various regional committees have been established to advise and investigate in different parts of the country, the only statutory committee is the Sheffield, Rotherham and District Smoke Abatement Committee. This consists of eleven members appointed from six constituent authorities, the medical officer of health for Sheffield acting as medical adviser.

Attitude of Industry

Many owners of plant are obviously indifferent to or ignorant of, the devices offered for the purification of their fumes. This impression is substantiated by the replies to a questionary addressed by a member of the society to the surveyors of a leading boiler insurance company whose business is stated to cover the whole of the British Isles. With few exceptions little interest was reported to be shown in the movement, and serious attempts to abate the nuisance were undertaken mainly through fear of prosecution. In very few districts was there any evidence of marked improvement in the knowledge of boiler attendants regarding the principles of smokeless combustion. Imperative demand for fuel economy had led to some improvement in very large plants employing skilled and trained engineers. In the majority of cases, when authorities complained of the emission of black smoke, the responsibility was shifted to the fireman. Since *force majeure*, even to a slight degree, has been found to have a certain effect, the suggestion has been made that persistent negligence should be regarded as a criminal offence, and that protective legislation should be introduced on the lines of the Factory Act, bringing smoke abatement within the jurisdiction of the Home Office.

Smoke Abatement in U.S.A.

It is instructive to consider the effect of the practical measures that have been adopted by certain States in America to deal with smoke abatement. Figures quoted by Mr. H. B. Meller, head of an pollution investigation in the Mellon Institute of Industrial Research, Pittsburg, show that 130 cities with a population of over 30,000 have some ordinance designed to reduce smoke. This usually takes the form of provisions requiring the submission of plans and complete specification to the appropriate authority prior to the erection or construction of furnaces or chimney stacks in buildings used for trade purposes. Greater discrimination is evidently being shown in the selection and use of equipment and fuel; plant owners and operators, recognizing that "smoke means waste," are learning to co-operate in its abatement. In consequence, consistently better results are reported every year. The subject, Mr. Meller states, is largely a matter of education—a necessity referred to in the first annual report of the society for 1930, and in the report on smoke abatement issued by the Royal Institute of British Architects at the beginning of this year. He stresses the fact, however, that *visible* smoke is not the only agent in atmospheric pollution.

Atmospheric Pollution

In this connexion the Department of Scientific and Industrial Research, which has published its fifteenth report[1] for the year ended March 31st, 1929, gives some precise information of deposits of different elements of pollution as recorded at various observation stations in this country. Compared with the average, a reduction of total solids was recorded at nineteen stations, and an increase at nine during the period of its investigation. Half a dozen stations reported increased deposits of sulphates and tar. In the previous report the data referring to these elements were stated to be probably the most reliable as an indication of smoke pollution. The highest mean monthly deposits of tar and sulphates were reported at Newcastle-upon-Tyne, where the heaviest deposits of ash and carbonaceous matter (other than tar) were also recorded. Taking the general average figure of each station as a basis of calculation, the highest deposits of tar and sulphates were recorded at Leeds and Huddersfield respectively. During the year an inquiry was instituted by the Research Committee into the problem of measuring sulphur impurities, and some evidence was obtained that sulphur trioxide may not be a normal constituent of the atmosphere, appearing only during fog. From the results of this investigation it is hoped to design an apparatus suitable for the routine determination of the amount of sulphur in the air.

Medical Aspect

A consideration of the smoke nuisance from legislative and scientific aspects may fittingly conclude with a reference to its deleterious effects on human life, especially in encouraging and aggravating disease, as in tuberculosis. This aspect of the matter is referred to by Dr. W. M. Willoughby in his annual report for 1929 as medical officer of health for the City of London, in which he also emphasizes the danger to health of suspended impurities retarding the evaporation of fog. Much of the damage and discomfort in the City of London he attributes to domestic smoke caused by burning household coal, and he suggests that a remedy may be found in smokeless heating by gas, electricity, gas or a smokeless solid fuel with proper regard to ventilation.

SATURDAY NOVEMBER 8TH 1930

THE DEVELOPMENT OF MENTAL HOSPITALS

At the first International Hospital Congress held in Atlantic City last year, Dr George W Henry, director of laboratories Bloomingdale Hospital, gave an interesting account of the development of hospital care and treatment of mental disease in America The text of his address has now appeared in the *Proceedings* of the Congress[1] He points out that in the period in which the early migrations to America were taking place Europe had not yet begun to emerge from psychiatric mediævalism At this period institutional care was provided by gaols workhouses and pesthouses and by abandoned monasteries which had been converted into asylums Such treatment was fast becoming the worst in the history of the civilized world, and it is no wonder that many of the afflicted preferred to wander about the country lured or driven here and there by invisible forces and dependent upon the charitable for sustenance The early colonists brought with them, therefore, the deeply rooted superstitions of the layman as well as the gross misconceptions of physicians regarding the mentally sick They were further handicapped by poverty, the rigours of pioneer life infrequent communication and the necessity of depending upon their own resources They were fortunate however in being less bound by tradition but their subsequent history indicates that they were not so free of the past as might be expected and that they were subject to the same errors and guilty of the same inhumanities as were their European brethren Ideas of demoniacal possession still held sway and near the close of the seventeenth century in the town of Salem fifty five persons were tortured and twenty executed as witches Some of the insane were confined in workhouses or gaols and those who became violent were kept in cages The feeble and helpless were distributed at public auction to the lowest bidder for their care

It is a relief to turn from these barbarous methods of dealing with the insane and defective and to follow Dr Henry in his account of the gradual improvement in the methods of dealing with mental illness It was only in 1751 that the law recognized insanity as an illness, and established the Pennsylvania Hospital for the relief of the sick poor and the reception and cure of the insane Dr Henry pays a generous tribute to the influence of Henry and Samuel Tuke in stimulating the beginning of a new era in the treatment of the mentally sick The kindly human interest which these two men had in their patients and their desire to aid others had a direct influence on the development of hospital care in the United States and led to the establishment of the Friends Asylum for the Insane and Bloomingdale Asylum— two living monuments to the Tukes which have never ceased to adhere to the ideal of moral treatment and have contributed greatly to raising the standards of institutional care in the United States In 1840 there were only eight public and four private hospitals for the care of the insane in the United States, the majority of the mentally sick being in poorhouses or in houses of correction At this time appeared another champion of the cause of the insane a woman of great strength of purpose and of untiring energy Dorothea Dix had been compelled to retire as a school teacher because of recurring attacks of tuberculosis but in 1841 she began to give religious teaching to female prisoners She found the conditions so shocking that she decided to make a personal investigation of other institutions She was peculiarly gifted in being able to discern fundamental defects in being governed by principles of action which were beyond criticism and in not being distracted by local or petty circumstances in attaining her goal During the forty years she devoted to this philanthropic work she was instrumental in founding or enlarging more than thirty State institutions for the proper custody and right treatment of the insane Within a few years after Miss Dix began her investigations signs of awakened interest in the mentally sick began to appear In 1844 the Association for Medical Superintendents of American Institutions for the Insane was established, and the *American Journal of Insanity* first published in that year became its official organ

Similar developments were taking place in this country about the same time In 1841 the Medico-Psychological Association was formed under the chairmanship of Dr Blake of Nottingham and in 1854 Dr A J Sutherland was elected as the first president and the *Journal of Mental Science* made its initial appearance Generally speaking it may be said that psychiatric developments in this country ran an almost parallel course with those in America Thus the establishment of a specially equipped pathological laboratory under the direction of a pathologist of recognized ability, at one of the State hospitals was announced in the year 1895 the same year that Sir Frederick Mott was appointed pathologist to the London County Council asylums and director of the pathological laboratory which had been established at Claybury Asylum for the purpose of research in mental diseases Mott was a great physician as well as pathologist, and his impressive researches exerted a profound influence upon the development of psychiatry in this country His aims were essentially practical and his work in relation to dysentery in asylum patients alone fully justified his appointment The American innovation was not at first very fruitful in results because the investigations carried out were too far removed from clinical problems When failure had become evident the work at the institute was reorganized under the direction of Adolf Meyer and with his advent in 1901 began a new era in institutional care and a new orientation to the problem of mental disease His teaching which requires that all factors —hereditary environmental constitutional physical social and economic conscious and unconscious—that have contributed to the life situation should be evaluated for the purpose of ascertaining the extent to which any or all of these factors may be modified and of rendering assistance in a better adaptation to the environment undoubtedly suggested many useful ideas on mental disease

Psychiatry no longer deals with fanciful abstractions but with very real human problems During the last few years Dr Henry observes psychiatry has become greatly stimulated through practical applications of knowledge acquired through the study of mental illness Psychiatric training and the habit clinics of the progressive child guidance

[1] Transactions of the First International Hospital Congress Atlantic City New Jersey June 1929 Paris 2 Avenue Velasquez. (Pp. 300.)

clinics in schools and industry, in the study of criminals and epileptics and the feeble minded, as advisers of the courts, and as consultants in general medical and surgical practice This wider recognition of the field of mental disorder has led to a realization of a need for increased flexibility of arrangements for dealing with it In addition to the public institutions for the psychotic patients, there is a need in the future for the development of psychopathic hospitals for patients suffering from transient, though perhaps severe and acute, psychotic episodes We have in mind the kind of patients now admitted to the observation wards of infirmaries where the facilities for treatment are generally recognized as falling short of modern ideals Overcrowding and the vision of prophylactic therapy have been potent factors in the remarkable psychiatric developments of recent years in America Dr Henry states that at the present time it would be impossible to care for the large numbers of mentally sick persons if it were not for the modern psychopathic hospitals and clinics in the cities, and no doubt the future will show similar developments in this country Equally important are the social service organizations, such as the After-Care Association in this country, for the guidance of the large number of patients who are being discharged from public institutions

It is undoubtedly both interesting and encouraging to trace the gradual development of our conceptions of mental disease and its treatment The progress made in recent years should act as a stimulus for increasing endeavours in the spheres of research, treatment, and care, for it cannot yet be said that psychiatric knowledge is sufficiently precise and clear-cut to enable suggestions to be made which are capable of effecting any striking diminution in the already considerable incidence of mental disorder in the community The problems of the psychiatrist are probably the most obscure—and possibly the most important—in the whole of medicine, and for this reason no efforts should be spared in seeking their solution

THE STUDY OF EPIDEMIOLOGY

At the annual meeting of the American Medical Association, held in Detroit last summer, an instructive address on "Neglected opportunities for epidemiologic study" was given by Dr E L. Bishop, State Health Commissioner of Tennessee [1] Dr Bishop's contention is that golden opportunities of study are wasted because, on the one hand, the connotation of epidemiology is so often limited to the control of acute diseases in epidemic form, and, on the other, it is thought that only specialists with awe-inspiring knowledge can hope to discover anything Hence, little of epidemiological importance is expected from field workers in local health services Dr Bishop points out that in fact some of the most important of epidemiological researches were carried out by practising physicians Budd, one of the great pioneers, was a provincial physician (like his master Bretonneau), and rightly pointed out that a country physician might have better opportunities for epidemiological observation than his town colleague, who living—epidemiologically speaking—in a dense wood, could hardly see the trees Similarly, local health officers are in a better position to undertake natural history studies of herd sickness than officials of a central authority, who may be forced so to spend their time that the sheer occasionally directed against them that they are mere "office epidemiologists," has a point

Dr Bishop has remedies, such as raising the status and increasing the financial resources of local health departments, which are excellent in their way, but the problem is rather more complex than he suggests He remarks that epidemiology "has for its major weapon specific items of information which it obtains from other distinct specialties, notably bacteriology, immunology, pathology, and statistics, and its function is the collection and analysis of these various specialized items of information, and finally the correlation of these items in such a way as to offer the broadest possible perspective with regard to the nature of the disease" We are by no means prepared to agree that this is a complete statement Such men as Snow and Budd, whom Dr Bishop holds up as exemplars, were primarily clinicians, and his specification omits what to them was of the essence of the matter in hand Still, what he does demand is a rare endowment—namely, the ability to co-ordinate, to set out in proper perspective, data gathered in various ways by experts, and described by them in what Mr H G Wells has called "the muffled and highly technical language of the really careful 'scientist'" This implies not only some knowledge of the several processes of technical investigation, but that kind of mental attitude which characterizes a really competent judge Does the current medical education of either America or this country encourage the judicial frame of mind? Professor H R Dean, in his valuable address which we printed in our Educational Number on September 6th, and some of our correspondents on the subject, are not altogether satisfied with the general education of the medical student Professor Major Greenwood, in his recent address to the Section of Epidemiology and State Medicine of the Royal Society of Medicine, is still more pessimistic The gravamen of the critics is that we are turning out young people with much special knowledge but little culture, technicians, not educated men It looks as though Dr Bishop were stimulating demand for a supply which is small and perhaps decreasing This defect is not peculiar to medicine "Our present difficulty," wrote Professor Watson in his life of Bishop John Wordsworth, "is that our students often attain to technical dexterity without acquiring the mass of knowledge which is needed if their skill is to be profitably employed" In other words, they are technicians, not men of liberal education

It is easy to point out a weakness, very hard to find a remedy Technical proficiency can be tested with reasonable ease If one demands that the student shall know "something about eyes," one can make reasonable sure that he *does* know "something about eyes," but it is not so easy to distinguish, by an examination test, between the cultivated intellect and the clever word spinner We might, like the French, profitably insist upon a higher standard of literary attainment in professional examinations, indeed, it is our duty to do so, but many men, medical and lay, who write well, reason ill However it is all to the good that attention should be directed to the fact that there is a demand for educated men rather than technicians in our profession, for nothing could be more disastrous than the belief, not confined to the field of epidemiology, that intellectual salvation is to be found in narrow specialization, and that the apocryphal surgeon of the last century, who, on seeing a physician enter his wards, said to his dressers, "Thank God, gentlemen, I know nothing of medicine," was a really wise man

THE EDUCATION OF MYOPES

One of the signs of the times is the care taken by statutory educational authorities of the children committed to their charge. It is no longer thought sufficient to provide one standard form of education applicable to all children, long and short, bright and dull. As a result of the lifelong efforts of Miss Charlotte Mason, founder of the Parents' National Educational Union, there is a growing appreciation of the fact that the child is an individual. Our forefathers recognized this, so they picked out those they judged fit to be educated. The risk of mass production in educational method came only when it was recognized that all children benefited by education, and the decision was made that all should receive that benefit. Nowadays, educational and physical grading is provided for. Special attention is paid to vision and its defects. There are admirable schools for blind children throughout the country with adequate accommodation, owing to the reduction of the incidence of blindness among the children. For over twenty years provision has been made by some of the larger educational authorities for children who are not blind but whose sight is too bad for them to be allowed to risk their following the normal curriculum. Most of such children are myopes. For them myopic or sight-saving classes have been established in many countries. The purpose of these classes is twofold (*a*) to provide a suitable form of education with a minimum of risk of eyestrain, (*b*) to endeavour to stay the progress of the myopia by improved conditions. The variations in the state of myopia over periods of time in young patients have been the subject of several records. A collection of 100 cases was made by Mr Priestley Smith[1] and reported to the Annual Meeting of the British Medical Association in 1901. In his paper is a remarkable graph showing the variations of the myopia over periods of five years these were taken from his private cases. In 1913 Mr Bishop Harman published[2] an analysis of 300 cases of high myopia in children in the London County Council myope classes. He gave a graph on the lines of that of Priestley Smith, which he thought showed that the average increase of the myopia was rather less in the London cases. There has lately been published, by the school medical officer of the East Ham Education Committee, a report on myopia by Mr C. L. Gimblett, based upon 170 cases treated in the ophthalmic clinic of that authority from 1923 to 1929. After giving an account of the conditions attending myopia, he considers its incidence as affected by sex, age, heredity, general sickness, school conditions, scholarship work, and the degree of defect. Among his conclusions the following may be cited. Myopia never gets better. All our efforts are directed to stop its getting worse, which tendency is at best only partially arrested, as is seen by the upward tendency of the curves of fourteen cases followed up for some years. Only one case of "congenital myopia" remained stationary, and that was true to type. In seven cases it was specially recorded that the onset of the myopia was preceded by a period of poor health and rapid growth. Mr Gimblett discusses the education of these children, and pays tribute to the myope classes initiated by Mr Bishop Harman. He states that the first of these was established in London in 1915, but the correct date is 1908. Mr Harman gave an account of the experimental working of the first of these classes at the London meeting of the Association in 1910.[4] West Ham started one of the classes for twenty children in 1923. A description is given of the working of the class. Mr Gimblett records that the myopes under his observation in the elementary schools even when given "easy treatment," or "oral teaching" under constant supervision, showed an increase of 0·4 dioptre a year, whereas a careful analysis of 150 cases in the London County Council myope classes showed a rate of progress of 0·2 dioptre a year. The paper is issued in official foolscap form, and with a wealth of charts and tabular matter that will make the editors of scientific journals covet the resources of a borough council.

READMISSION OF WOMEN STUDENTS TO KING'S COLLEGE HOSPITAL

On the recommendation of the medical board, and by a unanimous vote of the general committee, King's College Hospital, London, has decided to readmit women students to its medical school. They will be admitted, in limited numbers, from October next, the beginning of the school year. Mr C. E. Bedwell, the house governor, states that the action taken by King's College Hospital in 1928, whereby women students were excluded, was simply a protective measure, because it was feared that the closing of other hospital doors to women might result in an undue invasion of women at Denmark Hill, it was never regarded as an irrevocable step, but only as temporary and experimental. The objections to co-education which have been urged in some quarters, such as the supposed embarrassment felt by professors in teaching certain aspects of medicine to mixed classes, or the distraction of men students by the introduction of the feminine element have not been experienced at King's College. This action brings the number of London hospitals which admit women medical students up to three. The Royal Free Hospital (London School of Medicine for Women) admits women only, and in addition University College Hospital admits women to a limited number of vacancies not more than twelve each year, making between thirty-six and forty-eight women studying there at any one time. Some of the great teaching hospitals of London have always barred women students; in others the ban has been recently imposed, and in some of these a few women students who joined earlier are still working out their time. London is more conservative in this respect than the provinces, where co-education is the general rule. From statements made in the press by those entitled to speak for other teaching hospitals it does not appear that the example of King's College Hospital is likely to be followed immediately, but the action of King's gives point to a remark in our recent Educational Number that such a state of affairs as the ban upon women in the London medical schools can only be temporary.

NATIONAL INSTITUTE FOR THE DEAF

The National Institute for the Deaf (*formerly the National Bureau for Promoting the General Welfare of the Deaf*) has issued its sixth annual report, which gives an illuminating description of the efforts that are being made in this country, by propaganda and practice, to promote the welfare and interests of the deaf, including those whose sense of hearing has become deficient through accident or disease. Under the direction of the committee of the institute a number of regional associations have been established with the object of ascertaining the medical, educational and industrial requirements of deaf persons within their areas, so that the services of existing agencies may be made as complete and effective as possible. Associations have been organized in the northern, midland, eastern and western counties of England and in Scotland, and associations for London and the Home Counties are expected to be formed at an early date. Besides assisting and co-operating with the various local institutions and societies whose independence is being preserved, these associations take a particular interest in the prevention of deafness in so far as it can be mitigated or cured by early treatment.

prompt treatment—possibilities which the report states are much more frequent than is generally supposed The hardships which confront the deaf in obtaining employment and in adjusting themselves to modern industrial conditions are other problems which the committee intends to investigate more extensively by means of its regional associations Another matter of national importance is the teaching of lip-reading, not only to pupils in schools for the deaf, but to adults who have lost their hearing totally or partially in later life A proposal has been made to found a centre for instruction in this subject which would also be used for the training of teachers While the committee is not directly concerned with the actual work of schools, it supports their claim for adequate educational opportunities Most deaf children at present have no opportunities of receiving further education after they have left school at the age of 16 It has long been recognized by those who are interested in the education of the deaf that no means exist whereby parents, who cannot afford to pay the fees of private schools may obtain secondary education for their deaf children, however qualified they may be to take advantage of it A scheme for a secondary school, which will provide for the deaf the opportunities available to the rest of the population, has been prepared by the committee, and the hope is expressed that financial assistance will be forthcoming to put it into operation This subject is to be considered at a conference to be held at University College, Gower Street, W C, on November 12th, at 2 30 p m, when the report of the committee on the higher education of the deaf will be presented In a speech supporting the aims of the institute, Mr Stanley Baldwin recently deplored the widespread indifference shown towards the feelings of the partially deaf, who were made more sensitive of their infirmity by the ill concealed reluctance of people to speak to them He attributed this lack of sympathy to want of thought and imagination and appealed for that courtesy and consideration which was eagerly and habitually shown by all classes of the community in their behaviour towards the blind

THE PETER BENT BRIGHAM HOSPITAL

Hospital reports are seldom written in so interesting a way as is that of the institution where Professors H A Christian and Harvey Cushing are respectively the physician and the surgeon-in-chief [1] Though the phenomenal activity is shown by statistics and long lists of publications issuing from members of the staff and residents there, the reports of the heads of departments breathe a spirit of humanity, combined with suggestions as to future lines of research, which are rendered specially attractive by the absence of formality in the presentation An example of activity in a special clinic is the attendance in Dr W P Murphy's clinic for anæmia of 388 patients in the year under review, of the cases of Addisonian anæmia followed up two only relapsed, one from financial inability to obtain liver extract and the other from an inadequate dosage In Dr Reginald Fitz's diabetic clinic the effect of liver treatment for long periods of time has been very encouraging, in some cases keeping the urine free from sugar and maintaining the blood sugar at a normal level when previously large quantities of insulin had been necessary Further, the cause of the arterial disease so constantly present in elderly diabetics is under investigation, and it has been shown that angina pectoris and coronary thrombosis are not uncommon complications of diabetes Professor Harvey Cushing gives a list of seventy-eight publications from his department, and raises some questions of special interest, the first being that of the qualifications of future leaders in surgery Shortly before his death Dr R M Pearce of the Rockefeller Foundation asked the surgeon-in-chief of the Peter Bent Brigham Hospital if he would care to give a list of the probable leaders in ten to fifteen years' time, since such a collection in the various branches of medicine would indicate the value or weakness of the present system and be a guide to those who were influencing tendencies at the present time In reply, Professor Cushing declined to prophesy the leaders in the next generation of surgery and neurology, though he said he could easily name five surgeons and as many neurologists who might be expected to fill the part as future leaders any of them, however, might be stricken down by some stroke of ill-luck, or make a fatal *faux pas*, and Lord Haldane's dictum was cited as to the haphazard way by which people arrive at eminence and leadership In conclusion, Professor Cushing quotes his own reply to the frequent questions asked by students whether or not it was worth while to be both a house-physician and a house-surgeon The answer runs as follows "If you are going to be a surgeon it doesn't much matter, for you will have to treat every surgical patient medically as you go along, but if you are going to be a physician, by all means take a surgical house officership first, for you will not only learn what the surgeon can and cannot do, but you will acquire sufficient confidence and judgement to spare yourself from holding a surgical consultation whenever one of your patients gets a belly ache"

TRAINING IN MEDICAL RADIOLOGY

A special feature of the Second International Congress of Radiology in Stockholm two years ago was a meeting held to discuss teaching and training in medical radiology Twenty-three papers on this subject were submitted from as many countries, and these have now been brought together, with interpolated comments into one volume [1] Most of the papers are printed in German, the rest in English or French Dr Stanley Melville is responsible for the British section, and his communication deals largely with the teaching for the diplomas in medical electricity and radiology granted by the Universities of Cambridge, Liverpool, and Edinburgh A point of interest which emerges from these papers is that whilst Great Britain at the time of the congress had no chair of radiology, the United States had twenty-five full professors and nineteen associate or assistant professors and every other country represented had its professor of this subject On the other hand, Britain gives three university diplomas, and is apparently the only country to do this Since the Stockholm congress the University of London has established a chair of radiology, and has appointed Professor Woodburn Morison the first professor There is a good deal of very useful information to be found in many of these papers on the organization of tuition in radiology

A NEW ANTHRAX PRECAUTIONARY CARD

Anthrax, although so well known by name and by inquest reports on its victims, is a rare disease Since statutory notification became obligatory in 1895 only once (in 1916) has the number of cases of industrial anthrax exceeded a hundred in the year Hence its characteristic appearance in the cutaneous form developing about the third day into a central black eschar with a surrounding irregular ring of vesicles, is liable to be neglected by the workman and be wrongly diagnosed by the medical practitioner, unless the latter's attention is arrested by the fact that his patient's occupation is that of dock labourer, wool sorter, or tanner With internal anthrax, the only symptom of which usually resembles a prostrating influenza, the chances are that a diagnosis is only made by bacteriological examination after death Unfortunate happenings of this kind

[1] *Teaching and Training in Medical Radiology Acta Radiologica* Supplementum iv Stockholm 2 Editorial Secretary of the *Acta Radiologica* 1930 (Swedish crowns 20 for orders through booksellers, Swedish crowns 30)

have led the Factory Department of the Home Office to adopt the novel and salutary plan of issuing a card[1] with two coloured illustrations showing the appearance of the so-called malignant pustules on the first or second day, and on the third or fourth day. This the workman can carry about with him, and he is enjoined, if he gets a pimple, to take the card and "show it to the doctor." As in other bacillary infections, serum treatment, combined with physiological rest of the part affected, which is now commonly practised instead of excision, is the more successful the earlier treatment is commenced. The best known of these serums are Sclavo's, Evans Sons Lescher and Webb's, and Mulford's. The illustrations on the precautionary card have a historical interest, as the originals were painted some thirty years ago, at the request of the Factory Department, under the immediate supervision of Dr John Henry Bell of Bradford, who, in 1879, was the first to prove the identity of anthrax in animals with the so-called "wool sorters' disease."

JOINT TUBERCULOSIS COUNCIL.

At a meeting of the Joint Tuberculosis Council, held on October 18th, an announcement was made concerning the transatlantic tour undertaken this summer by fifty-one tuberculosis representatives, and financed by the Sun Life Assurance Company of Canada. In order to make the tour *more useful to participants and non-participants, it had* been decided to allot to various members a special section of the subject for them to observe, reflect upon, and write up on their return, so that when an institution was visited everyone's attention was alert and each visitor full of questions about his particular branch. The subjects chosen and to whom they were allotted are as follows: Dr L. T. S. Burrell, lipiodol and oleothorax; Drs. Dickinson and Clarke, methods of diagnosis; Dr F. H. Coutts, central tuberculosis administration; Drs. Peter Edwards and Goodwin, surgical treatment of pulmonary tuberculosis; Dr Fowler, drug treatment of tuberculosis; Dr Fletcher, methods of recording tuberculosis; Dr G. T. Hebert, pleural effusion; Drs. Jessel and D. A. Powell, local tuberculosis administration, including dispensaries; Drs. Johnstone, McDougall, and Stott, after-care work; Drs. Traill and Lloyd, chest radiography; Dr Martin, the treatment of non-pulmonary tuberculosis; Dr Pugh, the construction of hospitals and sanatoriums; Dr G. P. Price, the treatment of tuberculous pensioners; Drs. Rennie and Thompson, tuberculosis from the *public health viewpoint*; Dr *Stobie*, tuberculin and allied therapy; Dr Tattersall, preventorium work; Drs. Traver and Mayberry, advanced tuberculosis; Dr James Watt, sanatorium administration; Dr Wilson, bacteriology; Dr Wingfield, classification; Dr T. R. Elliott, methods of dealing with tuberculous pregnant women; Dr Dingley, training of nurses in tuberculosis work; Dr Allison, collection of diet, temperature, and other charts; Dr Blackmore, collection of photos; Dr Hefferman, silicosis; Drs. Wood and Holmes, light treatment; Dr Vallow, milk supply; Dr Trimble, haematology and Dr Sutherland, statistics.

FAMILY COUNCIL LAW

THE Eugenics Society has issued a survey[2] of certain measures of protection and control provided by different European countries for those classes of persons who, while neither insane nor feeble-minded, suffer from some degree of mental *instability* which renders them incapable of enjoying the full freedom of ordinary social life. In France, for example, the ancient family council system, consisting of six members of the patient's nearest relatives, is firmly established. The internment of an irresponsible person does not depend on medical certificates, but on the decision of the family council presided over by *the judicial authority*. The strict rules of the Code Civil and the existence of a public prosecutor in each district of France appear to make procedure smooth and effective. The "semi-interdicted," like the irrational spendthrift, may be controlled by the "conseil judiciaire" whose duties are described in detail. Germany considers the State as the prime guardian whenever a guardian is necessary, *although family councils* may be convened for special reasons. The functions of the Court of Wards and the working of the juvenile office are carefully stated. In the Netherlands the family council, as understood in France and elsewhere, does not exist. A system of guardianship, or curatela, supervises borderline cases, being very precise in its attitude to the spendthrift. In Italy the family council exists as a *permanent domestic* board, and its deliberated opinion is required for interdiction. The causes of its assembly, its composition, and its duties are fully described, along with the procedure of interdiction. Another form of guardianship—"inhabilitation"—is applied to the deaf and dumb, the congenitally blind, and where the unsoundness of mind is insufficient to justify interdiction. Scandinavia, here represented by Sweden, deals with its affairs by *Ministries* of State working through the district social and medical boards, assisted by councils of experts. The Temperance *Board gives much attention to dipsomaniacs*, and the marriage code forbids the union of the mentally unfit. The chapter on Scotland takes note of the Scottish practice of voluntary admission to mental hospitals, and the use of observation wards by several of the largest parish councils. The survey concludes with an exposition of the Lunacy Laws of England, a retrospect, and an analysis of the present situation with its difficulties and proposed changes.

MENTAL TREATMENT ACT: APPROVAL OF MEDICAL PRACTITIONERS

MEDICAL practitioners who desire to be approved by the Board of Control for the purpose of making recommendations in respect of voluntary patients under 16 years of age—Section 1 (3) of the Mental Treatment Act—and temporary patients—Section 5 (3)—can obtain the necessary form of application by writing to "The Board of Control, Caxton House West, Tothill Street, London, S.W.," and marking the envelope "M.T.D." in the top left-hand corner. As the Act comes into operation on January 1st next, intending applicants *should write for this form* immediately. The Board cannot entertain applications for approval from medical practitioners of less than five years' standing on the *Medical Register*.

THE next session of the General Medical Council will commence at 2 p.m. on Tuesday, November 25th, when the President, Sir Donald MacAlister, Bt., will take the chair and give an address. The Council will continue to sit from day to day until the termination of its business.

THE *Mitchell Lecture before the Royal College of* Physicians of London will be delivered at the College, Pall Mall East, S.W., by Dr. L. S. T. Burrell, on Thursday, November 13th, at 5 p.m., the subject is 'Indication for treatment in pulmonary tuberculosis."

THE annual dinner of the Society of Medical Officers of Health will be held at the Piccadilly Hotel, London, W., on Thursday next, November 13th, at 7.30 p.m. Reception at 7.10 p.m. The Minister of Health has promised to attend and the occasion will be in the nature of a domestic celebration of distinctions recently conferred on members of the society. The guests of honour will be Sir Eustace Hill, Dr. W. G. Willoughby, President Elect of the British Medical Association, and Mr. G. S. Elliston, M.C., M.A., on his retirement from the post of executive secretary of the society. Owing to absence abroad, Sir Andrew Balfour is unable to attend.

THE STATE OF THE PUBLIC HEALTH

SIR GEORGE NEWMAN'S REPORT FOR 1929

[FIRST NOTICE]

THE annual report of the Chief Medical Officer of the Ministry of Health[1] is always a vital document, but this year three of its twelve sections are of special importance in view of public agitation about one matter, some ill-informed criticism of another, and changes in public administration affecting the third. The sections are those which deal respectively with maternal mortality and morbidity, the insurance medical service, and the administrative effects of the Local Government Act. We propose in this first notice to deal with these three sections, leaving the other and more statistical parts of the report to a later occasion.

MATERNAL MORTALITY

During 1929 there were 643,673 births registered in England and Wales. The number of deaths classified as due to pregnancy and child-bearing was 2,787, and in addition there were 960 deaths of women not so classified, but returned as associated therewith. The total puerperal mortality (4·33 per thousand births registered) was only slightly below the figure for 1928 (4·42), which was the highest recorded since the classification came into use in 1911. The death rate from puerperal sepsis alone, apart from other puerperal causes, was 1·80, the highest recorded, except in 1920 when it was 1·81. "It is disappointing," says Sir George Newman, "to be unable to report any definite tendency towards reduction, especially as all investigation indicates that these figures might and should be substantially reduced."

An analysis of the figures in relation to locality shows that the northern districts of England have the highest maternal mortality rate. In London the rate is lower than in any other part of the country, a favourable position due in part to the number of maternity hospitals and medical and midwifery schools, but also in part to the smaller proportion of abnormal confinements. Rickets is less familiar in London than in districts of Lancashire and Yorkshire, and therefore there is less risk of pelvic deformity leading to difficult labour; also possibly some forms of toxaemia, causing eclampsia and haemorrhage, are more prevalent in northern industrial districts. The Midlands and South have almost invariably a lower maternal mortality than the North, though a Midland county, Huntingdonshire, has the highest maternal mortality in England, and Radnorshire the same unfortunate pre-eminence in Wales. Puerperal sepsis, as the report points out, is a disease of urban rather than rural life, but the other causes of maternal deaths, such as difficult labour, eclampsia, and haemorrhage, are such as call for prompt and skilled medical aid, which is more readily available in the large towns.

In writing of the interim report by the Departmental Committee on Maternal Mortality and Morbidity, Sir George Newman, who was its chairman, points out that in only 5 per cent of the deaths investigated by the committee was there an absence of reasonable facilities for effective medical care, but in 43 per cent there was an absence of ante-natal care, or errors of judgement by doctor or midwife, or negligence of the patient. "There is, and can be no allocation of blame or culpability, for all the circumstances and conditions are not known, but there is the clearest possible indication of the exact direction and focus of the necessary remedies. They imply amendment in the medical care of the individual mother." Three practical considerations emerge from the report of that committee and of the other departmental committee, on the training and employment of midwives. "First, there is an absolute need for effective ante-natal supervision of every case of pregnancy; secondly, there is a relative need for improved obstetric practice—on the part of doctors and midwives—ante-natal, at childbirth, and post-natal, and lastly, there is a relative need for the fuller completion of local organization to provide, and make available, all the necessary facilities for an effective service." Ante-natal clinics are increasing but as to maternity institutions, although the number is considerably in excess of what it was ten years ago, the bed accommodation is still insufficient to provide for all the women who may desire to be confined in the hospital, partly because there is an increasing demand for the treatment of obstetric complications which were formerly neglected or treated at home, as well as for the treatment of intercurrent diseases associated with pregnancy.

Contraception and the Position of Municipal Clinics

In view of the fact that some local authorities are now being urged by the advocates of contraception to provide facilities for its practice, four pages of the report are devoted to a very clear official statement of the position. It is pointed out that this claim is preferred at a time of falling birth rate, and when the provision for maternity and the treatment of conditions incidental thereto is receiving more skilled attention than formerly, alike in institutions under local authorities, in private medical practice, and in voluntary hospitals. "Birth control" is not a novel idea, it is only the means which have changed. Certain disadvantages attaching to an indiscriminate advocacy of artificial contraception are set down as, for example, that organized public instruction on the subject is liable to become propagandist and pseudo authoritative in presentation and impression, leading to a commercial exploitation of the means, that the effects of artificial contraception may be not only local and physical, but general, organic, and psychological, that the means may be deleterious in their effects, and (apart from sterilization) uncertain in action, and that such methods cannot be a substitute for social amelioration, self-control, or decent conditions of life. Organized instruction in contraceptive methods would be foreign to the purpose of a maternity and child welfare centre established by a local authority for expectant and nursing mothers. It is also considered doubtful whether there is at present a sufficient degree of unanimity in the medical profession or in public opinion *as to contraceptive methods to* justify a local authority supporting out of the rates a centre for systematic instruction. The Ministry's attitude is that the use of maternity and child welfare centres, including ante-natal clinics, for such a purpose would damage their proper work. In particular cases in which there are medical grounds for giving individual advice on contraceptive methods to married women in attendance at the centres, it might be given, but such advice should be limited to cases where further pregnancy would be detrimental to health, and should be offered at a separate session and under conditions such as would not disturb the normal and primary work of the centre.

THE EFFICIENCY OF THE INSURANCE MEDICAL SERVICE

The section on the insurance medical service begins with an assertion of the preventive value of the work of the general practitioner. It is pointed out that the general practitioner, *skilled in diagnosis, who detects tuberculosis* in the early stage and shows the patient how to avoid becoming a source of danger to others, has made an effective contribution to the prevention as well as the cure of disease. The same applies to detection of any infectious condition in the early stage, also to ante-natal care, and to much else in general practice. "The insurance medical service, in active operation every day for some 140,000 patients, has therefore, as I view it, an extremely important place among the agencies which are working for the prevention of disease."

The number of insurance practitioners in England and Wales in 1929 was 15,573, and the average number of insured persons on a practitioner's list was 932. It is estimated that 44 per cent of the men and 33 per cent of the women on the *Medical Register* in this country are engaged in insurance practice. Sir George Newman answers his own question as to how the efficiency of the

[1] *On the State of the Public Health.* Annual Report of the Chief Medical Officer of the Ministry of Health for the year 1929. London: H.M. Stationery Office. 3s. 6d. net.

service is maintained by saying that, first of all reliance is placed on the natural tendency of the doctor to do his best for his patient. As a rule patients are considerate of their doctors and do not make unnecessary demands upon them. As a rule doctors do their best for their patients. There are, of course, exceptions to both rules, but, as I see the position, they are few and far between." Other safeguards are free choice of doctor and the right to lodge complaints with an urgence committees. In 1929 there were 174 complaints against practitioners investigated by medical service subcommittees, and in thirty cases the Minister decided that remuneration should be withheld from the practitioner. Remuneration was also withheld from five practitioners for failure to keep proper medical records, and from eight for failure to furnish information required by the regional medical officer. Two formal representations were made by insurance committees that the continuance of a practitioner on the medical list would be prejudicial to the service, and in one of these cases the Minister removed the name. Sir George Newman recapitulates the procedure with regard to the checking of excessive prescribing. Under this heading in 1929 the number of practitioners interviewed by the regional medical officers was 1,359. In 147 cases a warning letter was sent to the practitioner by the Minister, and thirty cases were referred for investigation by panel committees, in twenty-eight of which it was found by the committee or on appeal by the referees that unnecessary cost had been incurred.

Increased Sickness Claims

The question of increased sickness claims and the controversy with regard to medical certification is again the subject of extended reference. There was a further increase in the number of such claims in 1929. Following on the report by the Government actuary on the examination of the sickness and disablement experience of a group of approved societies[1] two special investigations have been made—the first a scrutiny of the results of reference of insured persons by approved societies to the regional medical staff, and the second (the results of which are not yet available) an investigation of the actual condition of a representative sample of insured persons who were in receipt of sickness or disablement benefit on a given day. The first investigation involved a scrutiny of papers relating to 81,375 persons, being one-sixth of the total number referred during the year. In regard to each person it was ascertained what was the cause of incapacity as certified by the doctor, the duration of the incapacity at the time of reference, and whether, following the reference, the patient was deemed to be capable of work. The causes of illness set out on the medical certificate were grouped in four categories, and the patients were classified as to sex, and in the case of married women, as to age and marital condition. It was found that the proportion of persons who on reference ceased to draw benefit was highest among the married women of 45 and under, single women coming the next highest, and both of these were much higher than the men or the married women of 46 and over. The large proportion of persons who ceased to draw benefit when referred after a relatively short period of incapacity (the cause being set out as catarrh, chill, cold, influenza, neuralgia, and so forth) was also noteworthy. It is admitted—a very important point which seems to need all the emphasis that can be given to it—that in many of these cases if the patient had not been referred, a final certificate would have been issued on the first occasion on which the doctor saw the patient after the date when the reference was, as it happened actually made. But it is added that when full allowance has been made for this probability it is difficult to resist the conclusion that in many of these cases a final certificate ought to have been issued at an earlier date. The societies may be compelled for the protection of their funds to refer cases of this type to the regional medical staff at a much earlier age or illness than has hitherto been the practice of most societies. Whatever new facts may be brought to light it is held that there is room for further effort directed to the reduction of the number of unjustified claims for benefit.

[1] *Supplement* May 10th, p. 213.

Administration of the Local Government Act

Sir George Newman treats at length of the unification of health services under the Local Government Act, 1929. He points out that whilst the new Act calls for the active co-operation of the whole medical profession, and both enlarges and makes more serviceable the clinical applications of the science and art of medicine in many and varied directions, it entails in still higher degree an improvement in the medical and administrative work of the medical officers in the public service. The transfer of institutions to local authorities with ampler resources than the boards of guardians should imply a great improvement in the treatment of both acute and chronic sick. The traditions of British medicine as exemplified in the voluntary hospitals and in the best type of medical practice must become increasingly the routine practice in all these institutions.

With regard to the position and duties of medical officers of health, he thinks that their attention will be absorbed for a considerable time to come in the utilization and development of the transferred functions and institutions. Two fundamental objectives to be borne in mind are that the interest of the patient and the community must be paramount and that the administrative end must be the unification of all the public medical services of the area. The medical officer of health and his medical staff must be the normal responsible and primary advisers of the authority, and they should be so qualified and experienced and in such close touch with the medical practitioners of the area, as to ensure that their advice is safe, sound and competent. He mentions among other matters the appointment of local medical practitioners for outdoor or institutional service as one of the issues on which the medical officer of health should take such counsel as will better qualify him to offer timely and competent advice to his authority.

After some further discussion of the effects of the Act Sir George Newman reiterates the four principal medical points upon which the Act lays emphasis: the transference to 140 larger health authorities of functions hitherto belonging to 650 boards of guardians; the enlargement of the community of interest in State medicine; the change from an annual grant in aid to a "block" grant for health services; and finally the new standard of achievement which the Act sets up.

(To be continued.)

Ireland.

Public Health Reform in the Irish Free State.

THE Irish Free State comprises four county boroughs and twenty-seven administrative county areas with sixty-six urban districts. At the passing of the Local Government Act of 1925, with the exception of Dublin County Borough, there was no whole-time medical officer of health in the Irish Free State; to-day fifteen whole-time county medical officers have been appointed, besides assistant officers in various counties. Some aspects of this rapid progress in public health organization are described by Dr. E. F. Stephenson in a paper recently published in the *Journal of State Medicine* (vol. xxxviii, No. 10).

Central and Local Authorities

The Department of Local Government and Public Health, Dublin—to which Dr. Stephenson is chief medical adviser—was established in 1924 by the Ministers and Secretaries Act, and co-ordinates all the essential health services in the State, preventive and curative. It includes as an integral part of its administration the medical inspection and treatment of school children which is carried out through county boards of health and borough councils—an arrangement that has facilitated the initiation and development of county health schemes. Other circumstances that have simplified the consolidation of the medical services in a single department have been the exclusion, in 1911, of medical benefit under national health insurance and the abolition of insurance committees in 1929.

An effect of the Act of 1925 was to constitute county councils sanitary authorities for the entire rural area of each county. As such, their powers and duties are exercised through boards of health, consisting of ten members elected by proportionate representation. In addition to matters relating to public health, these county boards are charged with the administration of the Medical Charities and other Poor Law Acts—except in Dublin, Cork and Waterford. A board of health is empowered to appoint committees, such as public health, hospital and dispensary, and homes and homes assistance committees. This machinery is stated to promote efficiency and dispatch in the execution of business, while maintaining co-ordination between the services of preventive medicine, treatment, and relief as constituted in the central authority. Local health committees are also appointed at seaside resorts, small towns, and villages to deal with questions of domestic interest.

County Health Scheme

In describing the inauguration of county health schemes—which was assisted by the co-operation of the Rockefeller Foundation—Dr. Stephenson remarks that it is impossible to devise a rigid scheme that can be applied to all parts of the State, each county presents health problems peculiar to itself. Thus in the reorganization of rural health administration, tuberculosis demanded early attention in the counties of Cork, Wicklow, Meath, and Roscommon, where comprehensive schemes under the Tuberculosis Prevention (Ireland) Act were not already in force. Diphtheria immunization campaigns had to be started in Louth (Dundalk) and in certain endemic areas in Cork, where the supervision of meat supplies was also a prominent question. The eradication of typhus fever in Mayo, of enteric fever in Kerry and Galway, and of trachoma on the western seaboard are still outstanding problems. Practical demonstrations on the production of clean milk are contemplated in the principal milk-producing counties, such as Limerick and South Tipperary. Progress, therefore, must depend to a large extent on local conditions—for example, the character and distribution of the population, existing services and institutions, the financial resources available, and the ambition of the local authority. It was early perceived that an enlightened public opinion was essential before advance could be made in public health reform, and much of the success that has now been attained is attributed to preliminary educational propaganda through the press and by direct communications to local authorities dealing with the administrative, epidemiological, and economic problems involved. Statutory sanction was obtained by the Local Authorities (Officers and Employees) Act in 1926 for the appointment of county medical officers of health by selection boards set up by central authorities. This Act, which applies to all professional appointments, has apparently established a virtual State medical service in which local authorities have surrendered their previous patronage. Since the appointment of county medical officers of health, with supervisory powers over all sanitary officers, the responsibilities of district medical officers have been considerably curtailed. Their present duties include the notification of infectious diseases, the reporting of nuisances, etc., and they are employed, as dispensary medical officers, in the domiciliary treatment of tuberculous patients residing in remote places. Tuberculosis officers as such are no longer appointed. Experience has shown that in county areas outside the large centres of population ante-natal supervision and infant and child welfare can generally be carried out most effectively through the part-time service of nurses employed by district nursing associations. These nurses, who are supplied and inspected by the Queen's Institute of District Nursing, act as health visitors and as tuberculosis nurses in their respective districts, and attend to follow-up work in connexion with the school medical service. Excellent work in the prevention of sickness among school children is reported to have been done in Kildare, Louth, Offaly, and Cork, and schemes for a school medical service are coming into operation in other counties where medical officers of health have been appointed. Notable expansion has also taken place in the health services of county boroughs. In Dublin a whole-time medical officer has been appointed in charge of the maternity and child welfare arrangements, and closer co-operation has been instituted with the maternity hospitals of the city, while in the county borough of Cork one part-time official has been replaced by a medical superintendent officer of health, an assistant, and a school medical officer with appropriate staffs.

Food Supplies

Continuity in supervision of food supplies has also been established. By arrangement with the Department of Agriculture veterinary surgeons employed by sanitary authorities to supervise meat and milk supplies also discharge duties under the Diseases of Animals Act and the Bovine Tuberculosis Order over the same area. Arrangements have also been made that veterinary examiners under the Agricultural Produce (Fresh Meat) Act should be officers of the local authority, thus ensuring the soundness of the meat supplies for home consumption as well as for export.

Montgomery Lecture in Ophthalmology

The Montgomery Lecture in Ophthalmology was delivered recently in the Medical School, Trinity College, Dublin, by Dr. Francis S. Lavery, who selected for his subject the distribution and control of trachoma in the Irish Free State. He stated that reliable statistics of the incidence of trachoma in Ireland had not yet been compiled but that he had been engaged in this subject during the last twelve months. His investigations led him to conclude that trachoma was much more widely prevalent than was generally supposed. About a hundred new cases were treated annually in the Royal Victoria Eye and Ear Hospital, Dublin, but this was by no means an indication of the entire number of existing cases. His investigations among children in several institutions revealed that very many children were suffering from the disease. Those in charge of institutions often failed to recognize that there was anything wrong until almost irreparable damage to eyesight had been done. In one orphanage where he had found 23 per cent. of the children suffering from the disease, eleven fresh cases appeared during an investigation conducted eighteen months later. In urging the extension of school inspection and the establishment of special institutions for the segregation and treatment of children suffering from trachoma, he referred to the good work that was being done in the institutions at Swanley, Kent, and expressed the hope that similar institutions on a smaller scale would soon be established in the Free State.

Scotland.

Scientific Committee for Medical Investigation

A scientific advisory committee on medical administration and investigation has been appointed by the Secretary of State for Scotland, with the following reference: "To assist the Department of Health for Scotland in applying the results of scientific research to the details of public health administration and in promoting such medical investigations as come within the sphere of the Department or of the local authorities in Scotland." The members of the committee are as follows:

Alex. Bowman, D.Sc., F.R.S.E., Scientific Superintendent, Marine Laboratory of the Fishery Board for Scotland.

Carl Hamilton Browning, M.D., F.R.S., Professor of Bacteriology, Glasgow University.

E. P. Cathcart, C.B.E., M.D., F.R.S., Professor of Physiology, Glasgow University.

T. A. E. Crew, M.D., D.Sc., Professor of Animal Genetics, Edinburgh University, and Director of Animal Breeding Research Department.

Sir Walter M. Fletcher, K.B.E., M.D., F.R.S., Secretary to the Medical Research Council.

Sir Robert Greig, M.Sc., F.R.S.E., Secretary, Department of Agriculture for Scotland.

John Jeffrey, C.B., Secretary, Department of Health for Scotland.

J. Parlane Kinloch, M.D., Chief Medical Officer, Department of Health for Scotland.

A S M Macgregor, M D, Medical Officer of Health, Glasgow
T J Mackie, M D, Professor of Bacteriology, Edinburgh University
J J R Macleod D Sc., M B, Professor of Physiology, Aberdeen University
Robert Muir, M D F R S, Professor of Pathology, Glasgow University
J B Orr D S O, M D, Director of the Rowett Institute for Research in Animal Nutrition, Aberdeen
W J Tulloch, M D, Professor of Bacteriology, St Andrews University

Dr Parlane Kinloch is chairman, and Mr George Wallace of the Department of Health for Scotland is secretary of the committee The appointment of the committee follows on the conference of research organizations which was held in Edinburgh in November of last year, and at which Mr Johnston, M P, Under Secretary of State, presided A more intensive use of Scottish research material and the correlation of work in the biological sciences, having a bearing on medical as well as on agricultural, fishery, or other fields, were urged at the conference It was also urged at the conference that a scientific advisory committee would secure for community health purposes the application of the most recent results of medical research It will be noted that the personnel of the committee includes representatives of several branches of biological work

Reopening of Bridge of Allan Spa.

The spa buildings at Bridge of Allan were formally reopened by Sir Humphry Rolleston on October 30th The mineral waters of this resort have been known for upwards of 150 years, and in the middle of the last century the town received annually more than 30,000 visitors Gradually, however, the popularity of the spa began to decline, no doubt on account of the fact that the equipment of the wells house was not kept up to date, but a determined effort has now been made to restore its former reputation The town council acquired the property a few years ago, and investigations were made to ascertain whether the waters still retained their properties Among those consulted were Dr Judd Lewis, chairman of the Standard Measurements Committee of the International Society of Medical Hydrology, and Dr R Fortescue Fox chairman of the council of that society The results of analysis were so satisfactory that a scheme for renovation and modernizing was entered upon six months ago The new spa comprises a pump room for the sale of mineral water, a sun lounge fitted with "vita" glass, bathrooms for hydrotherapy, and a department for electrotherapy and inhalation The town council has arranged with the Allan Water and Spa Hotel, whose property adjoins the wells, to administer the establishment Bridge of Allan is situated about thirty miles to the north of Glasgow on one of the spurs of the Ochil Hills Sheltered from north and east winds it has a southerly aspect, and is easy of access from all parts of Scotland The journey by road or rail from Edinburgh, Glasgow, and Perth takes little more than an hour

Sir Humphry Rolleston's Address

The opening ceremony was performed in the sun lounge and the large company was presided over by Provost Dunbar Sir Humphry Rolleston, in the course of his address, said there was no doubt whatever that spa treatment did good, but exactly how this was brought about invited considerable discussion Obviously many factors might play a part, some of these were shared by all health resorts, whether or not they possessed any special waters, and whether or not they made full use of such advantages Thus a division of health resorts might be made into (1) those benefiting their visitors in a general manner on account of change of climate and atmospheric conditions, winds, pure air, sunshine and (2) spas exerting a specific influence in virtue of the internal and external effects of waters containing active principles such as certain salts Factors common to all health resorts included change of scene and all that this meant in mental rest and freedom from routine and worry a new physical as well as mental atmosphere bracing, dry or soothing, instead of the reverse, life in the open in place of an office or study There was much to be learned about the way in which mere change of environment did good or harm, quite apart from the healthy life and wholesome diet that should form part of a holiday The factors peculiar to individual spas were numerous and diverse, some being obvious at the first glance The chemical composition of the water and its temperature must, of course, be taken seriously into consideration The influence of iodine in water in preventing goitre was now well known, but much remained to be learned about the effect of minute quantities of constituents such as arsenic copper, magnesium, strontium, and barium in spa waters, especially when they were in organic combination Bridge of Allan had great natural advantages, its protected position resembled that of Cheltenham in the West of England and Montpellier in the South of France, and therefore its season extended from January 1st to December 31st The town council was to be congratulated on acquiring the wells with a view to restoring Bridge of Allan to its high position among the spas of Scotland An important factor in the permanent success of a spa was knowledge kept up to date by watchful investigation not only of the health promoting characters of the place and its waters, and of the methods of putting them to the best use, but also of the diseases which could with advantage be treated there Further—and this was a difficult problem, perhaps yet to be fully solved—how to recognize the constitutional peculiarities which determined whether or not a patient was likely to benefit from residence in the place, and what kind of treatment was suitable to each visitor These and other questions must be entrusted to medical advisers and on their decisions much must turn in establishing the reputation of a spa Bridge of Allan had a triple qualification for assured success—its climate, scenery and associations, the exceptional composition of its water, and a fine up-to-date equipment

Dr Fortescue Fox said that he had been interested for many years in the waters of Bridge of Allan and in the possibilities of the place as a health resort He did not know any spa which had been more thoroughly reported upon A new classification of waters had just been adopted at the Lisbon meeting of the International Society of Hydrology It was now proposed to group the waters of all countries on an organized method, and one of the examples set forth in a specimen register was the water of Bridge of Allan described therein as a chloride and calcium water

Changes in Scottish Public Health Administration.

Dr A S M Macgregor, medical officer of health for the city of Glasgow, delivered an address in Glasgow, on October 28th, dealing with the effects on public health administration of the Local Government Act 1929 In the new health organization, he said, nothing dramatic or novel was involved, there had been a consolidation of the various authorities, and the health committee of the corporation, for example, now administered a comprehensive service embracing in addition to the special hospitals administered under the Poor Law the mental hospitals and the medical inspection and treatment of school children This implied that such medical functions would in future be dependent on and related to one another and would advance in accordance with a concerted policy The Act went further than this, however, and embraced the institutional treatment of all sick persons whether they were under the Poor Law Acts or not Thus a large question had been opened up, since the local authority was now empowered to take into consideration all the sick within its area This meant that a careful examination must be made of the whole situation in association with the existing facilities provided by voluntary hospitals and other agencies The position of the latter was fully safeguarded under the Act, but there would be improved accommodation and medical service The Act involved a unified effort to place on a sound footing the medical services of the whole country, and it also made the preventive aspect the first consideration The suppression of smaller local authorities would enable health problems to be surveyed and solved in a more efficient manner, especially those concerning hospital accommodation for special purposes, which could best be dealt with by regional co-operation

Retirement of Edinburgh Medical Officer of Health

Dr William Robertson who retired recently from the post of medical officer of health to the city of Edinburgh was entertained at luncheon on October 30th by the Edinburgh Town Council and was presented with a set of the *Encyclopædia Britannica*. Lord Provost Whitson in making the presentation, said that Dr Robertson after acting as medical officer of health for Perth and Auchterarder, went to Paisley in 1898 as whole-time medical officer and thereafter held a similar post in the burgh of Leith for nineteen years. In 1920, after the amalgamation of Leith and Edinburgh he became assistant medical officer of health under Dr Maxwell Williamson, whom he succeeded in 1922. His tenure of office in Edinburgh had been most successful. In addition he had found time to contribute to various journals over fifty articles dealing with hygiene, and had written a number of standard books on health subjects. His lectures on sanitary law in Edinburgh University had been noted for their breadth and clearness of vision. Having now come to the end of his official career with the corporation, the members wished him a long and happy life in his retirement. In returning thanks Dr Robertson said that there were two types of medical officer—the academic official and the non-academic official, he considered that he belonged to the second category, for in his opinion it was necessary to get among the people if one wanted to have things done. He thought that no city in the United Kingdom had done more for public health propaganda than Edinburgh. What could be achieved by public health education was illustrated by the fact that in Edinburgh, with a population of 420,000, out of 24,000 gallons of milk sold daily 16,000 gallons were of high grade quality, while in Glasgow, with its population of over 1,000,000, only 2,000 gallons of high grade milk were sold.

England and Wales.

King Edward's Hospital Fund for London

The financial and vital statistics contained in the annual statistical review of the London hospitals for 1929, which has just been published by the King Edward's Hospital Fund for London, indicate that, so far as London is concerned the voluntary hospitals have never had a larger measure of public confidence since the first report was issued in 1903. At that date the figures related to 16 hospitals, the present report reviews the work of 138. The review opens with a table showing the extension of hospital work during the last five years. Since 1925 the bed complement has increased by 1,810, the average number of beds occupied by 1,550, while the number of new in-patients has increased by 38,000—10,900 in the course of the year. Although a decrease of 4,000 is recorded in the number of new out-patients, compared with the previous year, the number of out-patient attendances increased by 84,000. A reduction in the average period of residence has enabled a larger number of patients to take advantage of the services of the hospitals, which are no longer confined to the indigent sick. This remarkable expansion in volume of work has been accompanied by increasing financial support. Since 1925 the annual receipts from voluntary sources for all purposes, including receipts for building and endowment, have exceeded £2 000 000, while a record sum of £2,852,000 was received in 1929. The total income of all the hospitals dealt with in the review amounted to £3,600,000—an increase of £168,000 on the preceding year. In spite of an advance of £135,000 in the total expenditure, due to progress in various directions, including the addition of 380 new beds, the aggregate surplus of income over expenditure for the year was £50,000 compared with £17 000 in 1928. Income from legacies exceeded the figure of the previous year by £129 000. In the main divisions of ordinary income there was a decrease of £57,000 in donations, but an increase of £78 000 in receipts from patients, while the total ordinary income increased by £40 000. Details of income and expenditure are illustrated, as in the previous report, by coloured graphs and diagrams. The difficulties of the hospitals in recent years have not been caused by diminishing income but by increased expenditure which in 1929 amounted to £3 550 000 compared with £3 415 000 in 1928. Of the increase of £516 000 since 1925 approximately £400,000 has been due to extended service, the remainder being accounted for by the increasing cost of hospital treatment. It should be noted, however, that these rising costs reflect the expense of additional benefits given by the hospitals to their patients as a result of advances in medical and surgical practice. A comparison between the increased expenditure and the increased volume of work shows that the expenditure for 1929 increased by 4 per cent. over the previous year, and by 17 per cent. over that in 1925, the beds occupied by 2·9 per cent. over the previous year and 13 per cent. over 1925, while out-patient attendances rose by 1 per cent. compared with 1928 and 15·5 per cent. compared with 1925. Notwithstanding the fact that a larger number of hospitals had deficits during the year, the aggregate amount of the deficits was smaller, and the total amount of surpluses larger than in 1928. Copies of the statistical summary and review may be obtained from the offices of the Fund, 7, Walbrook, E.C.4, price 1s. each.

Tuberculosis in Lancashire

The importance of having an efficient dispensary organization in a tuberculosis scheme is strongly emphasized by Dr G. Lissant Cox, central tuberculosis officer for Lancashire, in his annual report for 1929. He points out that the objective of the dispensary work comprises early diagnosis and prevention, rather than cure, close co-operation with general practitioners and health officials being essential. A dispensary must be the centre of activity for a town or district in regard to measures for the prevention of the disease, the expert examination and diagnosis of cases, and the supervision and special treatment of all known tuberculous persons. For dispensary purposes the administrative county of Lancashire contains five large areas and two sub-areas. In each large area there is a chief dispensary co-ordinating the whole of the work, and branch dispensaries have been provided, there is also a pulmonary hospital containing about fifty beds for observation cases and the treatment of intermediate and advanced cases of pulmonary tuberculosis near the homes of the patients. The two sub-areas come under the control of the medical superintendents of the High Carley and Elswick Sanatoriums respectively. The report contains a small-scale map showing the arrangements of the dispensary areas in the county, and also a chart indicating the more important items for which the consultant tuberculosis officer of a dispensary area is responsible, the whole of the organization and work of one of these areas can thus be seen at a glance.

A considerable portion of this annual report is devoted to research work and new methods of treatment. The proportion of sanatorium beds for children in the administrative county is less than elsewhere, and the question naturally arose whether the fact that many children examined on suspicion of the disease, and rejected for treatment as being free from it, might result in early cases being overlooked, the beginnings of disease in later life being thus left to progress. A special investigation was therefore undertaken, and it was found that the rejection of 59 per cent. of the children up to the age of 15, who had been suspected of having tuberculosis, appeared to be fully justified. Of 1 084 young adults entered on the dispensary registers as new pulmonary cases, only 0·64 per cent. had been previously rejected in childhood by the tuberculosis officers. This very conservative diagnosis of pulmonary tuberculosis in children has resulted in the saving of public money, owing to the reduction in the number of sanatorium beds that it has entailed. In his previous report (for 1928) Dr Lissant Cox dealt at length with the inquiry into the fate of young children in tuberculous households and reference was made in the *Journal* of November 6th 1929 (p. 827), to the low figure of subsequent infection which was thus obtained. It is now mentioned that confirmation of the Lancashire results has been subsequently reported in the case of Leeds, while

an inquiry undertaken by the research department of the Brompton Hospital led to the finding that the percentage death rate within the first five years of life for children living from birth in contact with a parent whose sputum was positive is 2·6 per cent the corresponding figure for Lancashire is 2·7 per cent A study of the value of sanocrysin treatment has been continued and Dr Jessamine Cox is inclined to advise serious consideration of its use for patients who do not respond to ordinary sanatorium treatment Careful spacing of the intervals between the doses is necessary when reactions occur He find that the most obvious results are the effect on the sputum as regards the disappearance of bacilli and the improvement in the lesions in the lungs made manifest by skiagrams taken before and after treatment Another line of research which was followed was the value of irradiated milk in tuberculosis the results of the trial although limited to a few patients only did not seem to justify the introduction of irradiated milk as a routine part of sanatorium treatment Dr Cox adds, however that it is possible that a similar trial made on tuberculous patients living at home might have yielded different results, since many factors which obtain in the sanatorium regime are absent in home treatment even when coupled with dispensary supervision For example heliotherapy was practised at the institution where this investigation was conducted and it may be that an adequate amount of vitamin D was obtained in any case from that source

Artificial pneumothorax treatment has been proceeding satisfactorily, and is now classed as a most valuable adjunct to sanatorium treatment The special advantages thus gained were the more rapid disappearance of tubercle bacilli from the sputum the relief of symptoms in certain cases of bronchiectasis, and the diagnosis of obscure chest conditions especially new growths Its employment is said to be indicated in 10 to 15 per cent of admissions to a pulmonary hospital, and it was found to be especially useful in young adults who frequently responded poorly to ordinary sanatorium treatment Artificial light treatment at the dispensaries has continued to give satisfactory results, especially as regards patients suffering from tuberculosis of the skin and tuberculous adenitis with abscess formation and skin involvement The average cost of this treatment at twelve centres amounted to 4s 6½d per patient per week very considerable reduction in expenditure was thus effected, since a large proportion of the patients would otherwise have required treatment in residential institutions The cost of the tuberculosis scheme of the county council has amounted to a county rate of 1½d in the £, after making allowance for Government grants

Rheumatism in Childhood.

A Chadwick public lecture on rheumatism in childhood was given by Dr Gerald Slot on October 30th in the Great Hall of the British Medical Association with Sir Thomas Barlow in the chair Dr Slot said that the London County Council had found it necessary to institute a special department to deal with this problem In 1919 20 per cent of the invalidity of school children in London was due to tuberculosis, and 14·5 per cent to rheumatism in 1926 it was 12 per cent due to tuberculosis and 24 per cent to rheumatism and current figures showed lower tuberculosis figures and higher figures for rheumatism At least 25 per cent of the chronic invalidism in children was due to rheumatism and its terrible consequences—heart disease Tonsillectomy was of no proved value as a remedy Almost every case of recurrent rheumatic fever he saw had had tonsillectomy and it was not agreed that there was a higher incidence of inflamed tonsils in rheumatic children Some 15,000 cases of tonsils and adenoids were treated at LCC clinics last year Tonsils should not be removed merely because a child was rheumatic if there were no other signs of throat trouble Up to the present no specific treatment had been found but there were indications that calcium therapy might prove of real value The great step in prevention of rheumatism was the organization of rheumatism supervisory clinics several of which had been established in London and the provinces The clinic acted as a learning house consultative centre and centre for rheumatic research Working in conjunction with these clinics were the physically defective schools which formed an important and necessary link in the treatment of rheumatic children The problem of the after-care of these children was an urgent one various methods were tried by which they were taught trades suitable to their physical needs The ultimate solution of the problem depended upon a realization of the severity of the disease and its crippling effects Arrangements for adequate hospitalization and suitable methods of education proper work for the children on leaving school—all these were essential

Correspondence.

ROYAL MEDICAL BENEVOLENT FUND

Christmas Appeal

SIR,—Next month we shall be preparing to give as is our usual custom a Christmas Gift of £20 to each of our annuitants and to some of the most necessitous of the grantees These gifts are looked forward to by many Some of the regular recipients are blind, others are deaf, and many of them are old and infirm all are facing the hard lips of poverty Each year the number on our books increases and we need no less a sum than £550 this year if no one is to be left out

I appeal in plenty of time before Christmas, because we urgently need the money Will any reader who has not yet contributed please make his first Christmas Gift to this cause and thereby help a fallen colleague, or his widow or orphans? If he cannot give a large donation, may I ask him not to disregard my appeal but to send any sum however small to the Treasurer Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, W1—I am, etc,

London, W1 Nov 3rd THOMAS BARLOW

VACCINATION WITH BCG

SIR,—In the *British Medical Journal* of October 25th an editorial article has been published on Vaccination with BCG which informs your readers inaccurately of the reports read on this subject at the International Conference at Oslo Would you allow me to put things right please?

The ten reports which have been presented to the above-mentioned conference have unanimously asserted the perfect harmlessness of BCG The president of the German delegation Professor Hamel, has declared that BCG cannot be held responsible for the Lübeck disaster which is due to a contamination at Lübeck of the BCG strain sent by the Pasteur Institute in perfect condition not virulent for guinea pigs

On the other hand, Professor Neufeld director of the Robert Koch Institute Berlin has textually declared and published in the *Deutsche medizinische Wochenschrift* of September 19th 1930

If it be true that BCG vaccination can be but partially efficient we must not forget that it is impossible to inoculate more virulent bacilli in man and that is why BCG according to the actual state of our knowledge represent the minimum chance of success in antituberculous vaccination Calmette and Guerin have had the merit of putting such a vaccine at our disposal It is our duty in fighting this frightful disease to use every process based on sufficient scientific research work That is why I proposed that the authorities should introduce BCG vaccination in Germany on a larger scale as a trial especially in particularly exposed areas

When writing of Prof Troff's R and S colonies I failed from BCC the author of the editorial article in the *British Medical Journal* ignores that Professor Neufeld stated, in his report at Oslo that the Robert Koch Institute, having obtained R and S strain from Petroff had established the presence of virulent *Tuberculi bacilli* in R and S cultures and that consequently Petroff's experiments cannot be taken seriously nor Watson Cutler He added that in his opinion BCG is many times innocuous and the publications seeming to be in contradiction with the fact result from experimental errors Finally the writer of the article says to me that the vaccines Bu he forgets that they are the only ones that

immunize in a durable way, dead bacilli being only able to provoke ephemeral immunity Nobody fears Jenner's cow-pox vaccine, or Pasteur's hydrophobia, anthrax, or rouget vaccines, and they are *living* vaccines

Great Britain, Austria, and Portugal are the only European countries where as yet B C G vaccination has not been experimentally tried This is to be regretted, because evidence has been furnished at the Oslo conference that the *general mortality* is considerably lower in *vaccinated* than in *non-vaccinated* children—a striking proof of the innocuousness of B C G —I am, etc ,

Institut Pasteur, Paris, Oct 31st PROFR A CALMETTE

INDICATIONS FOR PERFORMING WILDE'S INCISION

SIR,—As no otologist, or other person interested in the aural complications of infectious diseases, has accepted Mr Burt Hamilton's suggestion (October 11th, p 619) that he or she should express an opinion on the value of Wilde's incision, may I now be allowed to reply to his letter?

First, let us drop the term "Wilde" and call it the "simple" incision, for Sir William told us to make it "at least an inch in length," and now we make it to fit the case, often a mere snick, not more than a quarter of that Next, how does this small operation fit in with the advance of medicine? There are no more corners of the body for surgery to assail, and we know just how much can be cut out We have now to learn how little we must do, and not how much we may do We have to learn the conditions for which a minor operation is enough where now we do a major The substitution of a simple incision for a mastoid operation in certain cases is an advance along these lines, and its possibilities must be closely scrutinized

So now for Mr Burt Hamilton He states that "one operation is better than two" As a surgical principle there must be many exceptions to this Other general principles come before it For instance, that big things should not be done where small are enough Even when the small thing has to be repeated it should still come first Witness washing out the maxillary sinus some half-dozen times And a simple incision for retro-auricular swelling is no bigger than that operation

Take another general principle That in acute illness one should deal with the acute trouble and leave the underlying disease for later This is equivalent to saying that under certain conditions, two operations are better than one I wonder how many persons have lost their lives because the surgeon did a primary resection of the gut in a case of obstruction instead of merely relieving the latter I have been so impressed with the value of this rule in the cases seen at the fever hospitals that I now apply it to those seen elsewhere I incise the swelling and do the mastoid operation about a week later I do this for the reason Mr Burt Hamilton gives—that when an "incomplete operation is performed" you do not get so good a result But it is the completeness of the bone work that matters The incision is but the means of access to this To operate across a mass of oedematous tissue, perhaps an inch in thickness, makes one much less certain of doing good work on the bone

I am sorry Mr Burt Hamilton thinks my two indications for doing the mastoid operation at once—namely, rigidity of the neck, and rigors—"do not materially alter the general proposition" I fear his dictum may prevent medical officers of fever hospitals from sending for otologists when they really are needed I am sure that the main reason why the otologist has been so long in getting foothold in the fever hospital has been the sweeping nature of his statements Medical officers in fever hospitals know that a simple incision does get a certain number of patients well When they meet an otologist who will admit that they may know something about the diseases in which they specialize and who is willing to try this method they reciprocate, and are willing to let him do the mastoid operation later in those cases where the simple incision does not cure, they also help him to sort out those few cases in which the major operation must be done immediately If an aural surgeon will not admit the value of a simple incision they will continue to do it without asking him, and if he adds that neck rigidity and rigors "do not materially alter the general proposition" they will continue to do it in these cases as well

I have only replied to Mr Burt Hamilton on matters of principle, in matters of detail we should probably come to a compromise, or even find ourselves in agreement after a half-hour's talk I have re-read my article, and see no reason to alter my assertion that in all cases of infectious disease in which retro-auricular swelling arises it is best to make a simple incision This is subject to the two exceptions quoted above, and to the fact that it is but rarely likely to be of value in the adult, as mentioned later in my paper Even though it may be a "very sweeping statement" I believe it to be true That it is a "very surprising statement" to one who has experience of ear disease in the infectious fevers is a matter of great interest to me It is also a matter of gratification, for it shows that the service of the council to which I have the honour to belong is in advance of the times in this matter, and has something from which others may learn —I am, etc ,

London, W 1, October 29th T B LAYTON

INVAGINATION OF DUODENAL ULCERS

SIR,—I have recently begun to deal with one variety of duodenal ulcer by invagination, or by raising folds on each side and burying it For the small ulcer, the first procedure is suitable, while for the larger kind, the latter method may be used The more severe operation of gastro-enterostomy is eliminated altogether The type of ulcer to which I refer is that which is non-obstructive, easily accessible, and situated on the anterior surface of the gut, at least half an inch from the pyloric ring, ulcers lying nearer the ring are, when buried, likely to involve or encroach upon the sphincter

This method of treatment is much on a par with that of simple closure of the perforating type of ulcer Very many of these cases are successfully dealt with year after year in surgical practice, in the great majority no further or later treatment is called for My results, so far, have been particularly satisfactory, but the number of cases is small Has any other surgeon adopted this method to any extent, and with what success?—I am, etc ,

Leigh, Lancs, Oct. 24th DONALD MACLEOD, F R C S ED

CONGENITAL RADIO-ULNAR SYNOSTOSIS

SIR,—Mr Bryan McFarland's letter in the *Journal* of October 18th (p 664) recognizes only two types of synostosis of radio-ulnar joint, he states that he cannot find in the literature any reference to the "dislocated head" type mentioned and described in my article I would like to refer Mr McFarland to John Fraser's *Surgery of Childhood*, from which I quote the following "The third type of synostosis is the 'dislocated head' type in which the head of the radius is well developed, but is displaced backwards or forwards" Also Abbott writes in *Surgical Diagnosis* (Graham) "In the latter type, the head of the radius is more or less normally developed, but is dislocated"

Mr McFarland states also that pronation through 90 degrees "completely precludes the possibility of the existence of a radio-ulnar synostosis" In reply I again quote Fraser "Flexion is normal, extension is limited, and pronation varies from 90 to 120 degrees", and this also is in direct contrast with Mr McFarland's statement that in radio-ulnar synostosis "flexion and extension are unimpaired"

Lastly, Mr McFarland suggests that the first case which I described is one of congenital dislocation of the radius, and not a synostosis In congenital dislocation only, supination is possible though an appreciable angle, whereas in the case described supination was not possible at all Abbott, in *Surgical Diagnosis*, states "It should be remembered that in a partial dislocation of the head of the radius, there is often fusion of the upper end of the radius and ulna"—I am, etc ,

Preston, Oct 26th. DAVID J DAVIES

PYREXIA OF UNCERTAIN ORIGIN

SIR,—Now that Dr Crookshank (November 1st, p 756) has entered the arena we may hope, under his guidance, to learn something from the discussion, and I would refer those interested to a more extensive presentation of his theme[1] reproduced in his *Epidemiological Essays*. His gibe against the systematists is a fair one, yet in the same paragraph he condones a systematist fallacy. Surely no toxin postulated by Dr Chalmers (October 25th, p 711) as the primary etiological factor in these epidemics is merely a sequel to pyrexia commonly observed in children, and particularly in the 'acidotic' type.

May those at present observing epidemics bear in mind Dr Crookshank's words—let us hear more from them when the field work is done! In my series the posterior root ganglion was the common cerebro-spinal localization, and no case developed signs associating it at all closely with the Heine-Medin group. I am, however, ready to accept this association, for Schall's[2] cases presented many features in common with those now under discussion. Batten in his Lumleian Lecture (1916), looks upon the inclusion of a neuritic type (VI) in the Heine-Medin group as not proven, but he writes: "The knowledge that a serous meningitis is present may not be of great value, but a serous meningitis of acute onset which rapidly clears up is strongly in favour of poliomyelitis."—I am, etc.

Stratton-on-the-Fosse, Bath, Nov 3rd. W. H. BRADLEY.

AVERTIN ANAESTHESIA

SIR,—In his letter published on November 1st Dr Parsons gives me convincing proof of the correctness of my deduction: his knowledge of avertin is second-hand, and he really does not understand the position. In the first place, no one who has any knowledge of anaesthesia would dream of using avertin for routine work. In the second place, the manufacturers when introducing avertin into this country described it as a basal anaesthetic and stressed the importance of not attempting to produce complete anaesthesia with it, its chief value, according to them, lay in its prevention of psychic shock. It also diminishes the amount of the general anaesthetic which may be given with it. To say therefore that "if avertin has to be given along with other anaesthetics the principal object of its use for routine work has disappeared," and that "if it has to be given in conjunction with another anaesthetic it ceases to be of primary importance" is to display a lack of knowledge of the subject which is startling. The statement about sodium amytal carries no weight as I see that Dr Parsons himself is reported in the *Lancet* (September 27th, p 694) to have said during a discussion on this drug at Winnipeg that the dosage appeared unsatisfactory.—I am, etc.

London, N.W.1, Nov 1st. FRANCIS E. SHIPWAY.

TUBERCULOSIS OF THE TONGUE

SIR,—I am interested in para 328 of the *Epitome* of October 11th, and also in the letter of Dr John R. Gillespie, which appeared in the *Journal* of October 25th (p 710). Lingual tuberculosis appears nowadays to be comparatively rare, and the following case may therefore be of some interest.

When the patient first came under my observation in hospital he had signs of extensive involvement of the lung. It was reported that he had had pleurisy about three months before, and thereafter a troublesome cough and purulent expectoration. The voice was weak, and examination of the larynx showed slight ulceration of the right vocal cord. Investigation of the chest revealed extensive disease in the left lung, with dry pleurisy in the lower part of the left side of the chest; there was also slight involvement of the right upper lobe. Tubercle bacilli were present in the *sputum*. Pain in the left side of the mouth was rapidly followed by the onset of ulceration on the under surface of the tongue within a few weeks; it had extended from the anterior pillar of the fauces along the left side of the tongue, reaching nearly to the *frenum*. The base of the ulcer showed some induration, and the surface was covered by greyish granulations. Slight oedema of the left cheek also developed and was persistent. The Wassermann reaction was negative.

The patient's condition became worse. In attempts to relieve the pain in the tongue several different local applications including orthoform and anaesthesin were tried, but little benefit resulted. Pepsin had ultimately to be made to swallow. Tuberculin therapy was deemed inadvisable owing to the extent and activity of the disease in the lung. After remaining in hospital for two months the patient went home and died there three weeks later.

It would be interesting to know how many of these cases of lingual tuberculosis are associated also with infiltration or ulceration of the larynx.—I am, etc.,

Rotherham, Oct 28th. E. ASHWORTH UNDERWOOD.

SIR,—The recent observations in the *British Medical Journal* regarding lingual tuberculosis have interested me. In an experience of tuberculosis lasting hardly as many months as your correspondent Dr J. R. Gillespie has years of service I have seen two cases of tuberculosis of the tongue.

The first was in a man aged 53 who had an ulcer removed in April 1929. The examination, was found to be tuberculous, and he was referred to the tuberculosis dispensary. He showed involvement of the right upper lobe and left apex, and was sent to a sanatorium where however he stayed only a limited time and made moderate improvement. Later the tongue showed a deep fissure at the tip to the left of the middle line and two superficial ulcerations on either side of the fissure. The condition was very painful at the beginning and the sense of taste was lost. He is now having x-ray treatment and some improvement can be seen. The ulcers look clean and healthy, there is no induration, the pain has been relieved, although the sense of taste is still lacking, and slight closing in of the edges is noted.

The second case came to my notice two weeks ago. This also was in a man aged 42. There is extensive and active disease in both lungs with a positive *sputum*. The larynx is also affected, and there is an elongated deep ulcer of the left side of the dorsum of the tongue. The edges are irregular, there is no induration, and no associated pain or loss of taste. His general condition is extremely poor, and the prognosis is certainly bad.

—I am, etc.,

Maltby, Rotherham, Oct 31st. WILLIAM LEE, M.B.

ABDOMINAL EMERGENCIES WHEN FLYING

SIR,—I was much interested in the report of Surgeon Commander Twigg in your issue of October 25th (p 687) on a case of perforation of duodenal ulcer when flying. Commander Twigg postulates this as the first recorded case of an abdominal emergency when flying. I should like to state, however, that in 1910 an airman was admitted to the Cambridge Hospital, Aldershot, immediately after landing from what was then considered a long flight from the West of England. He had acute abdominal symptoms, and I removed his appendix which had perforated under pinal analgesia. He made an uneventful recovery, and has since become famous. His case was recorded at the time in my annual report as surgical specialist to the Aldershot Command, and was subsequently incorporated in a series of 400 cases of operation under spinal analgesia reported in the *Journal of the Royal Army Medical Corps* for January, 1913.—I am, etc.,

Cheltenham, Nov 2nd. J. W. H. HOUGHTON, Colonel late R.A.M.C. (ret.).

TONSILS AND ADENOIDS

SIR,—Your leading article under this heading (November 1st) is liable to misinterpretation: there would be no so-called problem of tonsils and adenoids if the subject were dealt with on general surgical principles. In any given case if the palatine and pharyngeal tonsils are the site of chronic sepsis they should be removed: there is no question of operation dissemination. But to leave to itself septic untreated on the pleura or meninges is inexcusable.—I am, etc.,

Hove, Nov 2nd. T. S. ALLEN.

[1] *Lancet*, March 15th, 1919, p 609.
[2] Crookshank, *Epidemiology*, Vol. II, Kegan Paul, 1923–24, p 11.

PHYSIOLOGICAL RESEARCH AND CLINICAL MEDICINE

SIR,—In an address published in the *Journal* of October 11th (p 612) Lord Moynihan asserts, quite fairly, that physiology has a true mission "to elucidate the problem of the normal function of man's organs" Of course, it has a still wider range, in both the animal and the vegetable kingdoms, but the real point at issue is that chairs of physiology in this country were largely founded as an integral portion of a medical faculty, the older title of some of these chairs was "institutes of medicine" Since physiology professorships are held in some cases apparently by men who have no interest in the problem of the normal function of man's organs, Lord Moynihan is quite correct in saying "it is time to consider whether we should not now seek to establish chairs in hominal physiology" But Lord Moynihan must surely explain, when these chairs of hominal physiology are created, how hominal physiologists will be elected to them Will the pious founders of hominal physiology chairs be willing to envisage a conversion of their trust, and what safeguards has Lord Moynihan to suggest? Without them physiology chairs may be founded *ad infinitum* without securing his purpose —I am, etc,

Birmingham, Nov 2nd JAMES M MCQUEEN

KOCH AS CLINICIAN

SIR,—It would be difficult to find a more flagrant example of the *argumentum ad hominem* than that reported in your issue of November 1st (p 734) as having been made by Sir Almroth Wright at a meeting of the Medical Society of London on October 27th, when a remark about Koch led him to observe that "Koch was a very great man, but about the worst clinician—the worst doctor—it was possible to conceive"

It is not for the honour or credit of British medicine that this remark should pass unchallenged Anyone who knows intimately the history of Koch's work on tuberculosis, and especially anyone who has attempted to follow the gradual development of the subject in his mind as the successive points unfolded themselves, must feel the most profound admiration for the scientific imagination, inductive reasoning, clinical ability, and matchless endurance and tenacity compressed within the genius of the greatest of all general practitioners These qualities are surely the basic qualities of the best conceivable doctors and clinicians It seems probable that Sir Almroth Wright has sacrificed the canons of scientific criticism, on a subject in which he is keenly interested, for a misleading and damaging epigram —I am, etc,

London, S W, Nov 2nd. ROBERT CARSWELL

MEDICAL REGISTER

SIR —I desire to remind registered medical practitioners that if they wish to have a new address entered in the forthcoming *Medical Register* they should communicate with me without delay I should also like to take the opportunity of pointing out that the *Medical Register* is the statutory publication It is the appearance of a name in this book alone which makes a practitioner legally qualified and it should not be confused with other books of a similar nature, which are purely private publications —I am, etc,

NORMAN C KING,
Registrar General Council of Medical Education and Registration of the United Kingdom

44 Hallam Street Portland Place, W 1, Nov 4th

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE

At a congregation held on November 1st the following medical degrees were conferred

M B B Chir —J H Gibbens G J Gross W R F Wood
M B —H J Heathcote

UNIVERSITY OF LONDON

Professor G F Cask C M G, D S O, has been elected Dean of the Faculty of Medicine

NATIONAL UNIVERSITY OF IRELAND

THE Senate at its meeting on October 30th considered the reports of the examiners upon the results of the autumn examinations and awarded passes, honours, etc, in connexion therewith

The following awards were made Travelling studentship in anatomy E C Amoroso Dr Henry Hutchinson Stewart Medical Scholarships anatomy, M F Headon, physiology E Isaacson

Dr W M Crofton was reappointed lecturer in special pathology at University College, Dublin

The Senate decided that the Dr Henry Hutchinson Stewart Scholarships in arts in medicine and in mental and nervous diseases, should be offered for competition in 1931

ROYAL COLLEGE OF PHYSICIANS OF LONDON

A quarterly comitia of the Royal College of Physicians of London was held on October 30th, when the President, Sir John Rose Bradford, was in the chair.

Membership

The following candidates, having satisfied the Censor's Board, were admitted to the Membership of the College

Joges Chandra Banerjea M B Calcutta L R C P John Robert Blazé M D Lond Harold Ernest Brown M B Toronto Alfred Bramwell Cook M B New Zeal Charles Clifford Davis M B Lond, L R C P, Percival Cholmondeley Chalmers de Silva M B Lond, L R C P, Doris Louise Durie M B Lond L R C P Horace Lyans M B Lond L R C P Raymond Eustace Ford, M D Lond Traugott Ernest Gumpert M B Sheffield Francis Findlay Hellier M B Lond, L R C P Harold Percival Himsworth M B Lond, L R C P Mohamed Ahmed Ibrahim M B Cairo, Louis Philippe Eugène Laurent M B Lond L R C P, John Neil Leitch, M D Lond L R C P, Robert Alexander McCance M D Camb, L R C P, Owen Reginald Melwon L R C P George Osborne Mitchell M B Lond, L R C P, John Henry Mulvany L R C P Thomas Saint Martin Norris, M B Camb L R C P, James Vincent O Sullivan M D N U Irel, L R C P Trevor Kingsley Owen M B Sheffield, James William Reid M D Dalhousie Thomas Robson M D Lond L R C P, Harold Edmund Rykert, M B Toronto, Baldev Singh, M B Punjab William Wood, M D Aberdeen

Appointments

Sir Thomas Horder, Dr Comyns Berkeley, Sir William Willcox, Dr A G Gibson, Dr M A Cassidy, and Dr Carey Coombs were elected Councillors Dr Comyns Berkeley was appointed representative of the College on the Central Midwives Board Dr R A Young was re elected a member of the Committee of Management of the Conjoint Board, and Dr J A Nixon a representative on the Court of the University of Bristol

The President announced that Professor C C Okell had been appointed by the Council to be Milroy lecturer for 1932 and that the Jenks Memorial Scholarship for 1930 had been awarded to Frederick Basil Kiernander, until lately of Epsom College

GYNÆCOLOGY AND OBSTETRICS —Hilda M Lazarus

Obituary

WALDEMAR HAFFKINE C.I.E.,

Formerly Bacteriologist with the Government of India

By the death of Professor Haffkine there has passed away at the age of 70, a great scientist whose researches enabled him to produce first a cholera and later a plague prophylactic vaccine which are now effectively used wherever there is an outbreak of cholera or plague. His name will always be associated with this great achievement.

The history of the cholera prophylactic takes us back to Professor Koch's discovery in Egypt in 1883 when he found comma bacilli in the intestines of patients who had died of cholera, and in the rice water stools of patients suffering from cholera. Like all new discoveries, it was received with suspicion, even after his visit to Calcutta where he found in the patients suffering from cholera the same micro-organisms. It was not until he returned to Germany and an accident occurred in Professor Koch's laboratory in Berlin where a doctor engaged in cultivating the comma bacilli developed an attack of cholera and his discharges were found to contain comma bacilli, although no cholera existed in Germany at that time, that Professor Koch's discovery began to gain some support. Dr. Roux, who had been on the French Commission in Egypt in 1883, but owing to the decline of cholera had few opportunities of investigating the role of the comma bacillus and was somewhat sceptical as to its importance, had the advantage of working with Professor Koch in the epidemic of cholera in Toulon, in France on the part played by the comma bacillus as the causal agent. That investigation satisfied Dr. Roux that the comma bacillus was the causal agent of cholera, and since then it has always been acknowledged at the Pasteur Institute as being its real infective cause. The Pasteur Institute at that time made a special study of the preparation of vaccines and their application as prophylactics. This was due to Pasteur's discovery of vaccines against chicken cholera and against anthrax, a fatal disease affecting the cattle of France, and later a vaccine against rabies. An immense impetus was given to this line of research by Pasteur's great experimental demonstration of the value of his vaccine against anthrax at Pouilly-le-Fort, when before a gathering of scientists, landlords, agriculturists and medical men, out of 60 head of cattle he set aside 10, inoculated 25 with his anthrax vaccine, and left 25 uninoculated. Then he inoculated the 50 cattle with a malignant culture of anthrax with the result that the 25 uninoculated died, while the 25 inoculated remained as healthy as the 10 that had been untouched.

It was in an atmosphere such as this that Haffkine as a young man began his researches to discover a method by which a vaccine could be prepared that would protect the body against the poison elaborated by the comma bacillus. In nature the virus of infectious diseases such as small-pox and malaria is extremely variable, causing at one time a mild and at other times an extremely virulent disease. In small pox inoculations the virus which was obtained from the natural disease did not always give the same results. Sometimes a mild small-pox was produced and sometimes a dangerous kind. The method was abandoned when Jenner discovered a fixed vaccine in the cow pock produced on the cow.

The problem which therefore had to be solved in the preparation of a vaccine against cholera was to find the means of fixing the virus in a well-defined strength. Haffkine solved the problem. He discovered the means of engrafting the cholera microbe on animals and cultivating it indefinitely on such animals. This gave him his vaccine. At the same time he was able to increase the cholera microbe in strength which produced, with certainty, a specific infectious disease in animals and against which he was able to protect them. By this double discovery Haffkine, in addition to obtaining his vaccine, was able to demonstrate with the comma bacillus, as conclusively as Pasteur had done at the great demonstration at Pouilly-le-Fort, that he possessed a vaccine which would protect animals against a fatal disease caused by the cholera bacillus. The harmlessness of the vaccine was established by very careful and patient observations on medical men and scientists who were inoculated after the discovery. That was the first stage of Haffkine's research.

The next stage was to test the value of anticholera vaccination on human beings by observing its effect on communities where cholera existed in an endemic or epidemic form. Lord Dufferin, who was Ambassador in Paris and who had been Viceroy of India, was approached on the possibility of Professor Haffkine visiting India for this purpose. Lord Dufferin took a great interest in the matter and wrote to the Secretary of State for India and to Lord Lansdowne. With several letters of introduction Haffkine visited London, and availed himself of the opportunity of explaining his system to the leaders of the medical profession. His reception was of a most cordial nature. The English Government, through the Secretary of State for India, granted facilities for Haffkine to visit every part of India. I was home on leave at the time, and was asked by the Medical Department of the Local Government Board to give him every assistance possible when he was in Calcutta. Haffkine arrived in Calcutta in March, 1893, and after teaching my laboratory assistants the method of preparing the vaccines, as cholera was not very prevalent in Calcutta he accepted an invitation to Agra, where Hankin the Government bacteriologist, was anxious he should begin inoculations. In Agra 900 persons were inoculated. Once the inoculation were begun invitations from different places in Northern India came in so rapidly that Haffkine was unable to accept them all. Nevertheless, in the course of a year he inoculated about 25,000 persons. They were, however, too scattered except in a few places such as Cawnpore, Dinapore, Lucknow, and Goa, to allow of any careful observations as to their value. It was never theless noted in Lucknow, where a specially malignant cholera prevailed, that, among the East Lancashire and Royal Irish Regiments, who were attacked fourteen months after the inoculations the mortality, though lower among the inoculated, was much smaller than elsewhere. This was attributed to the fact that Lucknow after Agra was one of the first places in which inoculations were carried out and that they were done with great caution with only small doses between one-third and one-half, which were found later to be insufficient for full protection. Some months before the epidemic in Lucknow occurred it was decided that to obtain a thorough test it was better to concentrate at first as much as possible on Calcutta which contained a good bacteriological laboratory and assistants of mine who had been taught by Haffkine the method of preparing the cholera vaccine and the technique of the inoculation and who had prepared a quantity of the vaccine used upcountry. As soon, therefore, as the cholera season began in 1894, Haffkine came down to Calcutta and with the assistance of Dr. Chowdry, Dr. Chose, Dr. Chatterjee and Dr. Dutt, all able and reliable young men whom I placed at his disposal, the work began. The result of two years' inoculation and investigation showed that notwithstanding the incomplete protective effect of the first four days and the gradual disappearance of the resistance in those inoculated with a weak dose of vaccine which a large number of the inoculated people received during the first six months, the mortality among the inoculated compared with that of the uninoculated gave a reduction of over 72 per cent., or, in other words, in houses where inoculations were performed, and which were subsequently visited with cholera there occurred for every eleven deaths among the non-inoculated three deaths among a similar number of inoculated. This ratio improved later to a reduction of 80 per cent.

In addition to the evidence drawn from direct observation on man in epidemics of cholera proving the efficacy of the inoculation, an interesting set of experiments, carried out by Professor Koch, Professor Pfeiffer, and Dr Kolle in 1896, enabled them to prove in another way that the inoculations were protective They inoculated with Haffkine's vaccine a large number of students and doctors, and they found the serum of the inoculated had a rapid and absolutely destructive effect on the comma bacillus, exceeding in this respect by 200 times the power of the serum of ordinary individuals

Turning to Haffkine's work on his plague prophylactic, we now that he was fortunately in Bombay when the plague appeared in that city He was not altogether satisfied with his cholera vaccine, for he found that when an inoculated person was attacked with cholera the vaccine appeared to have little influence in preventing death The problem before him was therefore to prepare a vaccine for plague which should have the double effect—namely to preserve the inoculated person from an attack, and, if in certain circumstances this failed, to secure, if possible, that the attack should be a mild one This he endeavoured to obtain by preparing the plague vaccine differently from that of his cholera vaccine In a paper read before the Royal Society of Medicine in January, 1908 he gives the salient points of a ten years' experience of anti-plague inoculations in India as follows (1) It reduces the liability to attack to less than one-third of what it is among the non-inoculated (2) In the one-fifth of cases there is a reduction of the plague mortality by some 85 per cent of what it is in the non-inoculated Indians (3) That in an inoculated European an attack of plague, if it subsequently occurs, has so far always ended in recovery (4) That the inoculation is of very great value to persons already infected and incubating the plague, and prevents the appearance of symptoms or else mitigates the attack—a fact which disclosed the basis for the bacteriological treatment of the disease (5) That in natives of India the degree of immunity conferred by inoculation, though gradually diminishing, seems to last during several outbreaks of plague (6) In Europeans the effect has not yet been seen to disappear in the space of time since 1897 that this inoculation has been under study

Such is a brief sketch of the work of Haffkine I knew him intimately He stayed with us several times when in Calcutta, and on one occasion when he was ill with malaria, which he had contracted in Assam Whether ill or well, he was very likeable and always the same a courteous and amiable gentleman, even towards those who opposed him and attacked his views and work, very determined, remarkable for his powers of work, full of enthusiasm, and with a dauntless courage which was not to be damped by disappointments He had the supreme satisfaction before he left India of placing on a firm basis his anticholera and antiplague prophylactic We are proud to have elected him an Honorary Fellow of the Ross Institute, and to have his portrait in the library Ross and Haffkine are two outstanding figures in the beneficent work they have done for India, and the saving of lives from malaria, cholera, and plague in different parts of the world

W J Simpson

HUGH DICKIE, M.A., M.D.,

Chairman, Northumberland Panel Committee

The death of Dr Hugh Dickie, on October 22nd, after only two days' illness, has deprived Northumberland of one of its senior and best-known practitioners He received his medical education in the University of Glasgow, where he graduated M.B., C.M. in 1887, and proceeded M.D. in 1896 He went to Morpeth forty-two years ago as assistant to the late Dr William Clarkson, whose practice he subsequently took over In 1889 he was appointed medical officer of health for the borough, and continued these duties until his death, paying particular attention to the problem of slum areas For very many years he was medical officer to the Poor Law institution and to the parish of Morpeth, a public vaccinator, and referee and examiner for several large insurance companies He was chairman of the Northumberland panel committee, and a member of the county insurance committee A cause with which he had identified himself of late was the establishment of a new cottage hospital, and he himself raised a substantial sum of money for the provision of special equipment for it when erected A week before his death he attended a meeting of the building committee and learned that arrangements were being made for the purchase of the ground on which the hospital is to be built He was an active Freemason, and a past-master and director of ceremonies of the De Ogle and the Morpeth Lodges, being one of the founders of the last-named He was also a P.P.G.D. of the province of Northumberland, a member of the De Percy Chapter, and also of the Morpeth Lodge of Mark Master Masons He was the first Master of the Coquetdale Lodge, Rothbury, and one of its founders, at the time of his death he was I.P.M. For many years he was surgeon captain in the Morpeth Company of the 1st Volunteer Battalion of the Northumberland Fusiliers, and he held a temporary commission as major in the R.A.M.C. from 1915 to 1919 Always a zealous supporter of the British Medical Association, Dr Dickie was chairman of the Morpeth Division from 1922 to 1923, and a regular attendant at all its meetings He proved a stalwart in the various industrial struggles with regard to medical levies and other matters, while his advice in local ethical and other problems, being always sensible and temperate, was highly valued by his colleagues He loved all kinds of outdoor sports, at one time he was a keen lawn tennis player, and a member of the first club formed in the town He did much to encourage cricket locally and for a number of years was president of the Morpeth cricket club, he also took an active part in hockey and badminton He was chairman of the committee of the Morpeth Amateur Dramatic and Operatic Society, and left no stone unturned to make its performances successful A great admirer of Burns, and an enthusiastic supporter of the Morpeth Burns Club, he had on many occasions the privilege of proposing the toast to the "Immortal Memory" At the funeral on October 24th about forty medical practitioners were present, representing almost every district between the Tyne and the Tweed

Dr R A Welsh writes

The panel practitioners of Northumberland would like to put on record in the pages of the *Journal* an appreciation of what the late Dr Hugh Dickie did for them, and also of the affection and high regard they had for him He was chairman of the Panel Committee from the time of the inception of the Insurance Act till his death, except for a period during the war, when he was on military service As a chairman he was *facile princeps* He had a marvellous way with him, he knew when to pull up and to bring to heel an unruly colleague, but he did it with a smile and a humorous remark, without hurting his feelings He knew when a discussion had gone on long enough, though he did not hustle, he wasted no time He practised the *suaviter in modo* with the *fortiter in re* to perfection He was a many-sided man—a man with wide interests, thorough in all his undertakings, and a warm-hearted and loyal friend He was widely read both in English and in classical literature He met his friends and colleagues with a genial smile and a pleasant remark, but he had "an eye like Mars, to threaten and command"

The writer has known him forty years, and has often benefited by his clear vision and sound common sense The work he did for the insurance practitioners in Northumberland can never be told Every type of doctor, be he town or country, had his interests jealously guarded by Dr Dickie During our fight for an adequate mileage grant in 1914–16, it was his idea to have a large-scale map of the county prepared—some twenty-five square feet of canvas—showing every footpath, stream, and hamlet I was with him on a deputation to the Insurance Commissioners in London, and he took the map—the Whitehall officials had never seen such a map, the room was hardly big enough to display it—and I remember Dickie explaining to them that "while Old Gaul was divided into three parts, Northumberland was divided into two—a large industrial

part and a much larger rural one" That map and Dickie's speech on the matter had the most happy results, financially He had a wonderful sense of humour and a charming personality

His funeral was attended by about fifty of his medical colleagues from all parts of the county and Newcastle-on-Tyne There was ample proof of the esteem and regard in which he was held All business was suspended, all shops closed, and flags were at half-mast in the town of his adoption The streets were lined with all kinds of people, even the poorest of the poor, for he was kind and good to these in his time, and when we laid him in the earth we might have said of him, as Mark Antony said of the dead Brutus

> His life was gentle and the elements
> So mixed in him that Nature might stand up
> And say to all the world This was a man!

His passing, so tragic in its suddenness, has been a great shock to us, for he had been our guide, philosopher, and friend "We shall not look upon his like again"

Medico-Legal

OFFENCE AGAINST DANGEROUS DRUGS REGULATIONS £50 FINE.

At Ealing police court on October 29th, Dr Alfred Hugh Bell of Hanwell was fined £25 on each of two summonses charging him with having failed to enter in a register or daybook particulars of quantities of cocaine hydrochloride, contrary to the Dangerous Drugs Consolidation Regulations, 1928 He was also required to pay three guineas costs.

Mr *Vincent Evans on behalf of the Director of Public Prosecutions stated* that the transactions which led to the charge were two purchases *from different chemists in May and* July last one of 12 grains of the drug and the other of 20 grains on national health insurance prescriptions which Dr Bell himself took to the chemists It was alleged that neither of the insured patients in respect to whom the prescriptions were made out had received medicine containing the drug from him One of these patients in evidence said that Dr Bell had from time to time given him prescriptions which he had taken to the chemist but he had not been supplied by Dr Bell directly with medicine for the last two years Last July however the doctor gave him a lamp in which to burn oil to produce a vapour for inhaling he obtained the oil from the chemist. The other patient stated that she had had prescriptions from time to time but no treatment direct. One of the chemists testified that the first patient had been to his shop with prescriptions from Dr Bell for menthol with oil It was not usual for doctors to call and take away drugs themselves though they occasionally did so Dr Bell had handed in a prescription for 12 grains of cocaine alkaloid made out in the name of an insured patient and had himself taken away the drug Occasionally Dr Bell had given him orders for cocaine direct and supplies were given him on ten occasions Dr Bell had told him that he did not want his patients to know that they were taking cocaine The other chemist also stated that he had supplied Dr Bell with cocaine from time to time on his order He, too had been told by Dr Bell that he did not want his patients to know that he was prescribing cocaine He understood that Dr Bell was interested in a special treatment for bronchial troubles and it was quite feasible that he would want a considerable quantity of cocaine for that purpose

A *detective sergeant stated that on requesting* Dr Bell to produce his dangerous drugs register daybook or reference book he replied that he had none of these and had not obtained drugs from wholesalers since 1914 when he gave up dispensing He stated that he got cocaine and other drugs for his patients on signed orders at chemists sometimes on national health insurance prescription forms He obtained the drugs personally in this way so that he might incorporate the drug in a special treatment he was giving them for bronchitis and asthma

Dr Bell in evidence said that he had been a medical practitioner for nearly thirty years Four or five years ago he became interested in a special Continental treatment which involved the use of cocaine and this he obtained personally from the chemist because he did not wish his patients to know he was using the drug The supplies were obtained on written orders and national insurance scrip was used in some instances *because the patients* were insured persons on his list He stated that the first of the patients who had given evidence had had only a small lamp from him and that the other had been given inhalation though she had been ill and worried and had probably forgotten all about it *The witness added that* he had not thought it necessary to keep registers

The chairman of the Bench (Mr *Basil Holmes*) *in imposing the* fine said that the Bench was of opinion that a serious offence had been committed

Two other summonses for being in unlawful possession of 10 grains of cocaine hydrochloride and 12 grains of cocaine alkaloid on certain dates were dismissed

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT]

THE debate on the Address in the House of Commons closed on Tuesday, when a Conservative amendment was defeated by 281 to 250 The second reading of the Government's bill for raising the age of compulsory attendance at school was set down for Thursday

Maternity

In reply to Sir Basil Peto on October 30th the Minister of Health Mr GREENWOOD said that his first step to carry into effect the interim report of the departmental committee for the improvement of accommodation and treatment of women in childbirth would be to communicate with local authorities in *regard to certain recommendations* in the report. In cases of tuberculous patients he understood that special arrangements for confinement were not usually made in tuberculosis sanatoriums. It was generally preferable to transfer pregnant women from sanatoriums to maternity homes for the confinement and then to readmit them subsequently to a sanatorium. Asked by Sir Basil Peto to bear in mind the inadvisability of moving such cases from pillar to post Mr *Greenwood said* he was on the point of issuing a circular to local authorities on the whole field and the provisions that could be made Mr Greenwood told Mr Morris that no proposed to communicate with local authorities concerning certain recommendations by the Maternal Mortality Committee, not all of which required legislation

Mr GREENWOOD on October 30th told Mr Muggeridge that the number of midwives practising in a district was not the only consideration in deciding whether the council of the district should be the local supervising authority under the *Midwives Acts*

Experimental Work on Poison Gas

Mr *T Shaw replying to several members* on November 3rd said his attention had been drawn to statements that two *thousand old horses* had been handed over to the *experimental* station at Porton for experiments in poison gas and the cultivation of bacteria for spreading plague The facts were that during the period from 1921 to 1930 only 25 horses had been used for experiments at Porton in connexion with poison gas No horse nor other animal had been used at Porton for experiments in plague bacteria cultivation The experiments carried out were for preventive and curative treatment of horses affected by poison gases Between October 31st 1929 and October 31st 1930 729 animals had been used for experiments at Porton and 366 were killed by the experiments At the Physiological Laboratory at Cambridge from January 1st 1930 to October 31st last 85 animals were used for experiments and all were killed Officers holding vivisection licences for poison gas experiments at the War Department Establishment worked in strict conformity with the provisions of the Cruelty to Animals Act 1876

Animal Experiments

Mr CLYNES replying to Mr Freeman on November 3rd said that each holder of a vivisection licence was made responsible for seeing that any animal which was suffering pain that was either severe or likely to endure was at once killed if the main object of the experiment had been attained and that any animal that was suffering pain both severe and likely to endure was at once killed in any case. The requirement was made a condition of the licence and any infringement of it brought to his notice would be severely dealt with The Home Office inspector informed him that he was satisfied that the condition was scrupulously observed by the holders of licence

On November 4th Mr CLYNES told Sir R Gower that it was not his intention to introduce a bill this session to make painful experiments on dogs illegal

Bills

Bills presented in the House of Commons on October 31st by private members include

Hospitals (Relief from Rating Bill to grant complete or partial relief from rates in the case of certain hospitals

used for the purpose of hospitals infirmaries dispensaries convalescent homes nursing homes sanatoria and other similar uses or in connexion therewith presented by Mr Llewellyn-Jones, second reading February 6th

Slaughter of Animals Bill "to provide for the humane and scientific slaughter of animals and for purposes connected therewith" presented by Colonel Moore second reading December 12th

Advertisements Regulation (Amendment) Bill "to amend the law with respect to the regulation of advertisements," presented by Dr Vernon Davies second reading December 5th

On November 4th Mr Benson presented a bill to provide for the abolition of corporal punishment

---

Dental Benefit

Mr GREENWOOD told Mr Freeman on October 30th that he did not contemplate any change in the administration of the national health insurance scheme to include dental treatment for all contributors Approved societies with an aggregate membership exceeding 80 per cent of the total insured population already provide dental treatment for their members as additional benefit

---

Foot-and Mouth Disease—Dr ADDISON informed Brigadier General Brown on November 3rd that an outbreak of foot and mouth disease had occurred in connexion with which anti foot and mouth serum had been used The diseased animals and those in immediate contact on the premises on which the outbreak occurred, were slaughtered but cattle and pigs on neighbouring premises which had been exposed to infection received serum treatment None of the animals so treated developed foot and mouth disease

Pensions—Mr T O ROBERTS replying on November 3rd to Captain Wallace, said that independent medical experts had been appointed to advise in a special type of late claim for disablement He could not add any other specific class of case to the scope of their present duties

Health of Bakers—Replying to Mr Thorne on October 30th Mr CLYNES said that safeguards for the health of those engaged in the baking industry were at present regulated by the Bread Acts of 1822 and 1836 but enforcement was outside the power of the Home Office He was willing to consider proposals for fresh legislation but there was little prospect of time for a bill at present

National Insurance—Mr Greenwood expects to make an early statement concerning the position of insured persons who by prolonged unemployment, would cease at the end of the present year to be insurable under health insurance and contributory pension schemes

Physique of Recruits—Mr T SHAW in reply to Major Glynn said that from July 1st to September 30th 1930 10 447 men were served with notice papers for enlistment in the Foot Guards and infantry Of this number 6 506 or 62 per cent were rejected on *medical or physical grounds*

Medical News.

A GENERAL meeting of the Medical Officers of Schools Association will be held at 11, Chandos Street, W 1, to day (Friday, November 7th) at 5 p m Mr L E Barrington Ward, surgeon to the Hospital for Children, Great Ormond Street, W C, will read a paper on appendicitis, acute and chronic, in the schoolboy

THE annual dinner of the Prince of Wales s Hospital Reunion Association will be held at the Trocadero Restaurant, Piccadilly Circus W, on Thursday, November, 27th, at 7 45 for 8 p m, with Mr W E Tanner, F R C S, in the chair Price of dinner (exclusive of wine) 12s 6d, no tickets will be issued Members are asked to notify the secretary, Dr Bruce Williamson, 137, Harley Street, W 1, of their intention to be present, stating number of guests

THE West Riding Association of Graduates of the University of Edinburgh will hold their annual general meeting at 6 45 p m and dinner at 7 30 p m, on Friday, November 21st, at the Great Northern Hotel, Leeds Sir Norman Walker, M D, is to be the guest of the evening Any graduate requiring further information should apply to the honorary secretary, 33, Manor Row, Bradford

THE annual clinical At Home at the Royal Dental Hospital, Leicester Square, W C, will be held on Saturday, November 22nd, at 2 p m Cases of clinical interest illustrating the scope of the work of the hospital, especially the treatment of children and the young will be shown The various departments of the school will also be open for inspection Tea will be provided at 4 p m The annual dinner of the past and present students will take place on the same day at the Trocadero Restaurant, Shaftesbury Avenue, W 1, at 7 p m, when Dr Harvey Hilliard will preside

AT a meeting of the Hunterian Society in Cutlers' Hall, Warwick Lane, E C, on Monday, November 17th, at 9 p m, there will be a discussion on the place of the doctor in industry, in which Sir David Milne Watson, Mr W A Appleton, Professor E L Collis, and Dr Strickland Goodall will take part

THE *fifty fourth* anniversary dinner of the Cambridge Graduates' Club of St Bartholomew's Hospital will take place on Wednesday, November 19th, at 7 30 p m, at the *May Fair Hotel, with* Mr R Lester Moore in the chair The honorary secretaries are Dr H N Burroughes and Mr Reginald M Vick

A CONFERENCE on pollution of rivers and streams, arranged by the Royal Sanitary Institute, will be held at 90, Buckingham Palace Road, S W 1, on Tuesday, November 18th Professor A Bostock Hill, M D, will take the chair at 11 a m

A MEETING of the Illuminating Engineering Society will be held at the house of the Royal Society of Arts, John Street, Adelphi, W C, on Friday, November 14th, at 6 30 p m, when a paper on the lighting of offices and public buildings will be read by Mr J A Macintyre (H M Office of Works)

A COURSE of three public lectures arranged by the National Institute of Industrial Psychology (under the Heath Clark bequest), on modern views of nervous troubles, is being given at the London School of Economics and Political Science, Houghton Street, W C 2, by Dr Millais Culpin, on Wednesdays, at 6 p m Admission to the lectures is free and without ticket

THE Fellowship of Medicine announces that its M R C P course for this week comprises a lecture on November 11th entitled "Present views on renal disease," and another on November 14th, by Dr T Izod Bennett, on the relations of the colon and stomach in medicine, these lectures are delivered at the house of the Medical Society, 11, Chandos Street, Cavendish Square, at 8 30 p m, and tickets, price 10s 6d each lecture, are obtainable at the lecture room On Monday, November 10th, a free lecture, illustrated by lantern slides, will be given at the same place at 4 p m by Mr H P Winsbury White on modern diagnostic methods in surgical diseases of the urinary tract On the morning of November 12th, from 9 30 to 12 30, Mr Melvin McCullagh will give a free demonstration in gynaecology at the Samaritan Hospital for Women An afternoon and evening course in venereal disease at the London Lock Hospital will continue until November 29th From November 10th to 28th a course in medicine, surgery, and gynaecology will be held at the Royal Waterloo Hospital From November 17th to December 13th, at 5 p m, a series of lectures, illustrated by cases, will be delivered at the West End Hospital for Nervous Diseases, and an all day course in diseases of the chest will be given at the Victoria Hospital for Diseases of the Heart and Lungs from November 17th to 29th An all day course in diseases of the rectum will be held at St Mark s Hospital from November 24th to 29th Copies of syllabuses and tickets of admission may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W 1

A SERIES of post graduate clinics arranged by the University of Sheffield on the various manifestations of syphilis commenced at the Royal Infirmary, Sheffield, on October 24th, and will be continued on Fridays till December 12th, at 3 30 p m On November 14th Mr Ferguson will discuss ocular manifestations of syphilis The course is open free to medical practitioners

THE tenth annual conference of the Society for the Health of Women and Children of Victoria was held on September 9th, addresses were contributed by the Minister of Health for the State, the medical officer of health for the city of Melbourne, Dr Vera Scantlebury, Professor R Marshall Allan, and Dr J W Springthorpe, president of the society

A MEETING of medical men interested in physiotherapeutics was held at the rooms of the Medical Society of London on October 24th, with Sir Leonard Hill in the chair, when a resolution to form a society of physiotherapy was adopted Medical men and women specializing in any branch of physiotherapeutics who desire to attend the next meeting on Friday, November 14th, may apply for invitation cards to the acting honorary secretary, Dr R King Brown, 17, Featherstone Buildings, W C 1

THE new Turkish Baths provided by the Eastbourne Corporation in Carlisle Road are being opened to day (Friday, November 7th) at noon by Dr R Fortescue Fox

THE Minister of Health interviewed on October 30th representatives of several metropolitan Labour Parties and Trades Councils who had written to him on the subject of the imposition of test work as a condition of outdoor relief After hearing the general points put to him he promised to consider carefully any specific cases submitted

ON October 29th the National Medical Service Association met in London, with Mr Somerville Hastings M P, in the chair, and discussed the British Medical Association's Proposals for a General Medical Service

THE International Association for the Prevention of Blindness, which opened in Brussels on October 10th, received various national reports dealing particularly with the prevention of diseases and accidents which lead to destruction or impairment of sight

THE annual meeting of the council of the British Red Cross Society was held on November 5th, under the presidency of the Duke of York, when the report was presented by Sir Arthur Stanley In this attention is called to the continued success of the blood transfusion service and also to the health lectures which have been organized throughout the country It is hoped that a comprehensive scheme of co-operation of the various Red Cross clinics will be introduced soon The work of voluntary aid detachments has been steadily increasing, and there is now a total of 722 83 being composed of men and 639 of women British Red Cross detachments number 205 The existing textbooks have been revised and new manuals have been issued, including one on first aid and chemical warfare

THE hospital library of the British Red Cross Society and Order of St John (48, Queen's Gardens, Lancaster Gate W 2) now supplies over 4,000 hospitals of all kinds with books given by the public Development of this work as a permanent national scheme can only be carried out, however, with the co-operation of hospitals and public libraries In order to discuss this question a meeting will be held, at the invitation of the Public Health Congress, on Friday, November 21st, at 3 p m, at the Royal Agricultural Hall, Islington, under the chairmanship of Sir Arthur Stanley The speakers will include Mr L G Brock, chairman of the Board of Control; Mr H L Eason, M S, superintendent of Guy's Hospital, Dr Doris Odlum, of the National Council of Mental Hygiene, and Miss M E Sparshott, president of the College of Nursing

THE Minister of Health received a deputation on October 30th from the British Social Hygiene Council It was introduced by Mr Somerville Hastings, M P, F R C S, and included Sir Basil Blackett, Professor F J Browne Professor Bostock Hill, Mrs Neville Rolfe, and Mr E B Turner F R C S The deputation urged the importance of further propaganda on the subject of venereal disease and asked the Minister to issue a circular to local authorities pressing them to greater activity in this matter The Minister undertook to consider carefully the suggestion made to him

A GIFT of one million dollars has been made by Mr George Eastman, owner of the Kodak factories in America, for the establishment of a large and modern dental clinic for the benefit of the school children of Stockholm up to the age of 16 years The clinic is to be administered by the municipal authorities of Stockholm on the same lines as the corresponding institutes in Rochester (N Y), London, and Rome, established through similar generous donations by Mr Eastman

THE Health and Cleanliness Council (5, Tavistock Square W C 1) has had so many applications for publications dealing with verminous conditions that the Advisory Board has produced two leaflets on the subject These leaflets will be supplied free of charge to medical officers of health sanitary inspectors, health visitors, superintendents of infant welfare centres, and similar public health officials for use in connexion with their work

THE Minister of Health has issued a memorandum—37/T (revised)—describing the amended forms of the annual reports to be furnished by the chief (administrative) tuberculosis officers of local authorities in respect of the year 1931 and subsequently Simplification has been introduced as regards the reporting the work of tuberculosis dispensaries it will now be possible to show more conveniently the results of the observations of doubtful cases and the immediate results of the treatment of definite cases in residential institutions

A REPORT of the proceedings of the conference on the administration of the Mental Treatment Act 1930 convened by the Board of Control in July, has been published by H M Stationery Office, price 2s The principal addresses and discussions at the conference were described in the *British Medical Journal* of August 2nd (p 190)

TWO further series of eight brochures Nos 220 to 227 and 228 to 235, have been issued by the International Labour Office in connexion with its encyclopaedia *Occupation and Health* The brochures relate respectively to pottery industry, feathers, file-cutting, fire lighters (rosin) firemen gardeners and market gardeners, glanders hotels and restaurants hydroxylamine, factory surgeons fatty substances, first aid, fishermen gases and fumes gold gold mines, and homework They are obtainable from the London office of this organization, 12, Victoria Street S W 1

AN appeal for generous subscriptions to maintain and extend the work of the British Dental Hospital is made in its annual report for 1929–30 Since the hospital was established in 1911 its threefold policy has been (*a*) to establish centres for the treatment of persons unable to pay the ordinary charges of dental surgeons (*b*) to educate the public in oral hygiene, and (*c*) to assist associations and public bodies to provide education and dental treatment These services, the committee states will have to be curtailed in the absence of increased public support During the year skilled dental treatment at moderate cost was given at various hospital centres to patients who were not entitled to benefit under the National Health Insurance Acts In addition dental facilities were provided, in conjunction with a number of Metropolitan Borough Councils for the treatment of expectant and nursing mothers and young children At the Lewisham dental clinic over 5,000 attendances of children from the London County Council schools were reported during the year This centre also carries out the inspection of school children suffering from ear and throat affections The committee has continued to develop its welfare work in other directions, particularly in the treatment of adolescents at reduced fees In this connexion proposals are being considered by which special arrangements will be made with firms and businesses for the dental treatment of their employees.

OF the last 6,000 inmates of Sing Sing prison 4 822 of whom were whites and 1,178 negroes 1,061 gave a positive Wassermann reaction in the proportion of 12 per cent for whites and 41 9 per cent for negroes

DR JUAN CARLOS NAVARRO, an eminent Argentine paediatrist, has been elected president of the Academy of Medicine of Buenos Aires

PROFESSOR GUSTAVO PITTALUGA, director of the laboratory of parasitology at Madrid, has been nominated director of the Spanish National School of Hygiene

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR British Medical Journal British Medical Association House, Tavistock Square, W C 1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager British Medical Association House Tavistock Square W C 1 on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9551 9552 9553* and *9561* (internal exchange four lines)

The **TELEGRAPHIC ADDRESSES** are

EDITOR OF THE *BRITISH MEDICAL JOURNAL Articulate Westcent London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc.) *Articulate Westcent London.*

MEDICAL SECRETARY *Medusoid Westcent London.*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus Dublin* telephone 62550 Dublin) and of the Scottish Office 7, Drumsheugh Gardens Edinburgh (telegrams *Associate Edinburgh* telephone 24361 Edinburgh)

QUERIES AND ANSWERS

Stainless Steel Cooking Vessels.

"T M" having found objections alike to aluminium and to enamelled pans will be glad to know from anyone having had experience of them whether cooking utensils made of stainless steel are entirely satisfactory from a health standpoint.

Angioneurotic Oedema

H C B asks for advice in the treatment of a case of angioneurotic oedema occurring in a young married woman the attacks having commenced since her marriage Attempts have been made to detect a foreign protein in the food but without avail and there is no reason to suspect sensitization to semen She has been treated with calcium adrenaline, and ephedrine, the last of which has helped slightly She is often unable to leave home, owing to the face and feet being the areas where the swellings occur At present she has one swelling round each eye, and one in the lower lip, and one on the tongue is just disappearing She has had two abortions, the Wassermann reaction is negative

Climate of Madagascar

C R inquires about the suitability of Madagascar for a patient who has no disease but is not robust

*** The climate of Madagascar is very variable There is much rain on the thickly wooded east coast, which is unhealthy The west coast is drier, warmer, and has a smaller annual variation of temperature The south west suffers from drought The climate of the high ground in the interior is generally mild, healthy, and suited to Europeans

Constipation in a Child

MR PAUL BERNARD ROTH (London, W) writes In reply to K A, who wants to know how to treat constipation in a child, I have never found abdominal massage fail to cure this condition in a fortnight

DR E A FREYWIRTH (London, W C) writes In reply to "K A," the complaint is suggestive of congenital megacolon (Hirschsprung's disease), and I suggest an x ray examination before doing anything else The origin of the complaint from birth, with the relative absence of other complaints, makes me think of this somewhat rare condition Has the child meteorismus, or distension of the abdomen?

Iodine in the Treatment of Exophthalmic Goitre

MR CECIL A JOLL writes in answer to the query published on October 25th (p 716) There are very real dangers in the persistent use of iodine in exophthalmic and other toxic goitres The improvement which follows iodine medication is a temporary one, and, after a time, the symptoms reassert themselves with their former severity Meanwhile the thyroid gland becomes harder, and pressure symptoms may become added When this phase is reached further improvement by medical measures becomes almost impossible, and surgical intervention is rendered more hazardous Iodine, in my opinion, should be given purely as a means to preparation for surgical treatment, and if the latter is not contemplated, it is much wiser to avoid this drug altogether

Income Tax

Post Graduate Course

"C D G" last year attended a post graduate course on radium therapy, incurring certain hotel and travelling expenses Can they be deducted for income tax purposes?

*** No The expense of improving the means of earning income has to be regarded as capital outlay, and that principle applies to the improvement of professional knowledge or skill in the same way as it would to the improvement of the material equipment of a business or practice

Cost of Upkeep of Instruments

J A A R' inquires whether a deduction is allowed for wear and tear and depreciation of instruments, or whether only the cost of replacement is allowed

*** It has to be remembered that in no case can depreciation be allowed and also the cost of replacement—the former represents the *anticipation* of the latter The rules of Schedule D provide for the allowance of any sum expended for the supply, repair, or alteration "of any implements, utensils, or articles employed for the purposes of the trade, profession" etc It is clear that the cost of replacement of such articles should be claimed, and therefore that depreciation is not allowable This does not apply necessarily to large items of machinery or plant, including the car used professionally

LETTERS NOTES, ETC.

Addison's Disease

ANY medical practitioner in charge of a severe case of Addison's disease is invited to communicate with the *Medical Registrar, London Hospital, Mile End, E 1*, with a view to trial treatment with a cortical extract

Testimonial to Sir Ronald Ross

WE printed on September 13th (p 456) a list of donations received between May 1st and August 26th in response to the appeal on behalf of the Ross Award Fund Further contributions have been received since then from among others, Mrs Berger, Ceylon per Mrs Kindersley, Mrs. E Robinson, and Dr K B Shroff Bombay, amounting in all to £217 9s 1d The total amount received up to October 31st was £14 329 7s 7d The following analysis of the fund up to the end of October has been furnished by the honorary secretary

	£ s d
Home Fund	7 555 19 7
Singapore Straits Times	3 366 13 7
Government of India	2 000 0 0
Penang Gazette Press Ltd	654 0 0
Government of Rhodesia	262 10 0
Ceylon per Mrs Kindersley Kandy	214 9 1
Government of Cyprus	200 0 0
Malayan Daily Express	75 15 4
	£14 329 7 7

Donations to the Fund should be sent to Lloyds Bank, Ltd 110, High Street, Putney, S W 15

"All Liver and No Legs"

DR HILI AITKEN (Rotherham) writes to say that, although formerly scornful of the above dictum on the motoring doctor, he was rapidly converted when he discovered that he himself was a sufferer As a fortunate coincidence the self starter of his car ceased to function, and the consequent efforts of using the starting handle in the old way were of much greater effect than a vigorous course of physical "jerks," restoring both liver and legs to normal function

Schlatter's Disease

WHAT is usually known in the English literature as Schlatter's disease was independently described twenty seven years ago by Robert B Osgood of Boston (*Boston Medical and Surgical Journal*, 1903 cxlviii, 114) and by Karl Schlatter of Zurich (*Beiträge fur Klinischen Chirurgie*, 1903, xxxviii, 874), so that the eponym, 'Osgood-Schlatter's disease, adopted by the *Quarterly Cumulative Index Medicus*, appeals to the historical mind Both authors regarded trauma as the main etiological factor in the condition, and in a second paper (*Beiträge*, 1908, lix, 518) Schlatter again expressed his belief in the traumatic nature of his disease He was careful to disown cases of complete separation of the epiphysis, a condition with which surgeons had been familiar in pre Röntgen days (Poland *Traumatic Separation of the Epiphyses*, London, 1898, p 816) Knowledge of the natural history of the disease has advanced but little, and its position as a clinical entity has yet to be established In an interesting paper in the *Archives Franco Belges de Chirurgie* (1926, xxix, 119) M van Neck records a case of Schlatter's disease affecting the patella His hope that he had made an original discovery was shattered when he found that this condition had already been described in the Scandinavian literature by Sinding-Larsen and by Johansson An article in the October number of *St Bartholomew's Hospital Journal* entitled Schlatter's disease before and after Schlatter an eponymic note," quotes a passage on "enlargements of the tubercle of the tibia in young people much given to athletic games, from Sir James Paget's *Studies of Old Case books*, which seems to show that Paget in 1891 was familiar with 'Schlatter's disease as we know it

A Warning

A CORRESPONDENT in Yorkshire, acting on the advice of the chief inspector of police, asks us to publish the following description of a man who is wanted on many charges in different counties, and appears to have made a habit of seeking advice from doctors without any intention of paying their fee "Aged 48, heavily built, weighing about 16 st Well dressed, usually stays in a good class boarding house or small hotel Goes under such names as 'A Foster' and 'A L Brown', almost always uses the initials 'A' or 'A E' He usually complains of gout and seeks advice about a tophus, which has broken down and will not heal in the soft tissues of the right heel The margins of the ulcer are rounded and hard Near this sore he has an old incision scar, where a previous tophus was removed The fingers of both hands are much enlarged with gouty deposits" Any medical practitioner who is consulted by a man answering to this description should report at once to the local police

Cleansing of the Chalice

THE REV A C PURCHAS (Lyttleton, New Zealand) writes In connexion with the correspondence in the *British Medical Journal* on the 'Cleansing of the chalice' a doctor friend tells me that he always carries with him a small phial of brandy in which he cleanses his clinical thermometer, alcohol over 10 per cent being deadly to all germs That percentage, being present in Communion wine, should effectually destroy any possible germs that your correspondents so much dread Is it not the fact also that clergymen, who have to consume whatever wine remains in the chalice, and should therefore be the recipients of all manner of germs, are, as a general rule, extremely healthy—a witness to the almost negligible danger from such a source?

Vacancies

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals, will be found at pages 45, 46, 47, 48, 49, 53, and 54 of our advertisement columns, and advertisements as to partnerships, assistantships and locumtenencies at pages 50 51, and 52

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 211

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine.

409 Cardiac Hypertrophy and Dilatation of Pulmonary Origin

J Hatziegang (*Ann de Méd*, July, 1930 p 158) remarks that cardio pulmonary pathological conditions, though less well known have the same importance as cardio renal ones Functional troubles or anatomical lesions of the lesser circulation cause a hypertension, with resulting hypertrophy of the right side of the heart The diagnosis of this condition is usually difficult Hypertrophy of the right ventricle is particularly manifested by a sclerosis of the pulmonary artery, and also, but not so regularly, by a sclero-emphysematous process in the lungs, accompanied by extensive pleural adhesions and thoracic deformity *All processes* arising in the pulmonary artery or pleuro-pulmonary apparatus can cause a very pronounced hypertrophy and dilatation of the right heart Other important predisposing causes are the constitution and age the hypertrophies are especially noted between the ages of 35 and 45 in hypersthenic persons In addition to the pleuro pulmonary lesions, a sclerosis or discrete atheroma of the intrapulmonary arterioles has often been found after death The absence of this vascular change does not exclude the possibility of a hypertony of the lesser circulation, which, probably due to a short circuit of this circulation, has the greatest effect on the right side of the heart It causes a distension and hypotonicity of the muscular fibres ending in dilatation, due to increased blood content On radiological examination, pronounced discrete, pulsatile shadows are seen the pulmonary field being filled with adhesions The pulmonary arch protrudes, the rounded apex of the heart being found above and behind with the transverse diameter predominating Very frequently, especially at the onset, the prominence of the pulmonary arch alone is noted Two distinctive anatomical points between hypertrophy of the right and left sides of the heart are absence of aortic dilatation in the latter, and marked hypertrophy and dilatation of the auricle in the former Clinically hypertrophy of the right heart is marked by its prolonged evolution with repeated asystolic crises

410 Economic Results of Diabetic Treatment.

B D Bowen (*Journ Amer Med Assoc* August 23rd, 1930, p 565) presents a study of 81 cases of diabetes, treated by modern methods which was undertaken to determine the completeness with which insulin restores the diabetic patient to his former physical and economic level The subject is approached from the standpoint of the patient s total reaction to his environment rather than by applying specific tests The cases comprised (1) those under insulin treatment for a sufficient time to bring about apparently maximum improvement, (2) those free from interfering complications, and (3) those sufficiently intelligent and co-operative to answer questions Observations were made of the body weight, insulin dosage, period under treatment sense of well being reaction to physical exercise and to mental activity, change of occupation because of diabetes, earning capacity, and of the age factor From this study it appears that the adult diabetic patient who is treated with insulin compares quite favourably with the normal individual with the exception that the majority have the subjective impression that they are not capable of normal physical effort without fatigue, children, apparently, do not show this physical limitation Early recognition and adequate treatment are the most important factors in obtaining good results Various causes of the fatigue are suggested Improper dieting may be concerned, and the diets advocated by Joslin Sansum, and other authorities are mentioned Opinions differ concerning the role of carbohydrates and fat in energy metabolism Some believe that fat must be converted into dextrose before becoming a source of energy, while others hold that fat may be used as such without this conversion The diabetic patient may have some inherent metabolic perversion whereby he stores fat with greater ease instead of using it as energy The great tendency to fatness shown by insulin treated patients is a matter of common experience obesity is well known as a forerunner of diabetes Diabetic children are not usually over weight and do not get fat with insulin since they do not manifest any reduction in physical energy it is possible that they use their muscle glycogen for energy, and do not convert it into fat, a contrast with what occurs in some adults

411 Hepatic Cirrhosis with Cholesterinic Ascites.

C B Udaondo and A Vadone (*Rev Sud Amer de Méd et de Chir*, July, 1930 p 681) state that all serous effusions contain a certain amount of cholesterin especially is this the case in inflammatory exudates In pleural effusions the quantity ranges usually between 0 008 and 0 133 per cent, and under certain conditions this quantity may be greatly exceeded Cholesterinic ascites has been described by several writers in one instance the percentage recorded was 4 2. In the case recorded by the present authors the patient was a widow aged 62 She had noticed a gradual increase in the size of her abdomen for six years, this was accompanied by emaciation and general debility The performance of paracentesis once a year gave temporary relief On admission she was tapped and 31 6 pints of fluid were withdrawn this fluid was sero-fibrinous, with a glittering appearance due to innumerable cholesterin crystals amounting to 5 per cent of the total exudate The liver and spleen could not be felt but a mobile tumour as large as a mandarin orange could be felt in the right flank. The Wassermann reaction was negative The authors could not obtain any history of alcoholism, although they suspected it They remark that the etiology of these cases is obscure The exudates are usually aseptic but in some cases tubercle bacilli have been found

412. Dogs as Typhoid Carriers.

G Krogh Lund (*Ugeskrift for Laeger*, August 28th 1930 p 821) spent a year and a half in Jakobshavn North Greenland and investigated in the summer of 1929 the capacity of sledge dogs to be carriers of typhoid bacilli While the Greenland dog scorns the faeces of its own species its appetite for those of human beings is such that, for generations the inhabitants of Greenland have used no other method for their disposal It follows that if dogs are capable of harbouring typhoid bacilli in their intestines for long periods they may well spread the infection over wide areas in the course of sledge expeditions Twelve healthy adult dogs were obtained from homes where there had been no cases of typhoid fever Their faeces were examined at the beginning of the experiments, and the Widal reaction of their blood was noted It was positive in one dog in a 1 in 10 dilution, and it was negative in the remainder Some of the dogs were fed with the faeces of human carriers and others with cultures of typhoid bacilli The dogs were killed after the investigations had lasted between three and four months and typhoid bacilli were then sought in various organs, including the digestive tract and in the blood In as many as three of the six dogs fed with typhoid cultures typhoid bacilli were found in the gall bladder in pure culture from five to ten weeks after the last feeding with these bacteria The gall bladders in these cases were slightly inflamed Typhoid bacilli were also found in four cases in the dogs faeces, in some cases as late as three weeks after the latest feeding with typhoid cultures. In the case of one dog fed on the faeces of a human carrier, typhoid bacilli were found in the dog s faeces Krogh Lund suggests that the Greenland sledge dog may well play an important part in the dissemination of typhoid fever the danger is particularly great for children whose hands and faces are apt to be licked by dogs which have just eaten infected human faeces

413 Etiology of Juvenile Rheumatism

N Gray Hill (*Brit Journ Child Dis*, July–September 1930, p 161) thinks it probable that 1 per cent of all children below the age of 14 in this country develop rheumatic carditis All forms of rheumatism especially chorea are commoner in girls than in boys, this contrasts with adolescence and adult life in which acute rheumatism is as common in the male Between the ages of 7 and 12 years there is the gravest risk of an attack of acute rheumatism, but up to the age of 30 attacks of acute rheumatism or rheumatic fever are fairly common According to Hill s experience heredity has little if any etiological significance There does not appear to be any definite evidence of a distinct rheumatic type of child No special racial incidence was noted in Hill s patients A considerable proportion were undernourished on admission to hospital As regards climate the complete absence of acute rheumatism in the Tropics seems to indicate that a persistently high temperature has a deterrent influence on its production In this country it is generally agreed that first attacks or exacerbations are most frequent in the darker months of the year As regards home conditions, the incidence

of rheumatism is heaviest among children living in damp houses Hill's experience does not confirm the view that there is an intimate relation between tonsillitis and acute rheumatism, nor did he find any connexion between scarlet fever and rheumatic fever He concludes that acute rheumatism can be prevented or its incidence very considerably reduced by children living a healthy life on a simple diet, rich in milk, fruit, and animal fats, and being exposed, very lightly clad, to sunlight and open air

414 Whooping cough Carriers

THE current opinion is that whooping cough bacilli disappear five to six weeks after the termination of the disease M STOLZOVÁ SUTORISOVÁ (*Bratislavské Lekarske Listy*, October, 1930, p 482) describes a case of a girl, aged 3, in which whooping cough bacilli were found two years after the termination of the whooping cough In another instance large numbers of whooping cough bacilli were found in the nasopharynx of a child seven weeks after the termination of the disease The prolonged presence of the bacilli is explained by an inadequate production of antibodies The author concludes that the possibility of whooping cough infection through bacillus carriers must therefore be borne in mind

415 The Diagnosis of Poliomyelitis

W WERNSTEDT (*Kinderarzt Praxis*, September, 1930, p 3) emphasizes the importance of certain signs of nervous irritation in the diagnosis of incipient or abortive poliomyelitis Of these the most important are (1) rigidity of the neck and often of the whole of the back, both on active and on passive movement, (2) intermittent or persistent pain and tenderness in the legs and sometimes other parts of the body, and liable to be mistaken for rheumatism or neuritis, and (3) symptoms of ataxia, usually of the cerebellar type and confined to the lower limbs, and occasionally associated with some degree of spasticity If symptoms of this kind occur during an epidemic of poliomyelitis or in association with other typical cases in the summer and autumn, and other diseases can be excluded, the patients should be regarded as suffering from poliomyelitis and be treated accordingly

Surgery.

416 Healing in Bone Tuberculosis

THE method of healing in any infection of a joint in which there has been bony destruction may be primarily classified under two heads by fibrous union or replacement of eroded bones and cartilage by connective tissue, and by new bone formation in and about the joint M B HANSON and I FENGER (*Radiology*, September, 1930, p 374) deal with that class in which new bone formation is demonstrable during the stage of repair In arthritis deformans and in purulent involvement of joints quite marked new bone formation usually occurs, also in tuberculous joints in which there has been sinus formation with consequent invasion by secondary organisms It has been taught that new bone rarely, if ever, occurs in the repair of tuberculous joints other than those Cofield, in 1922, drew attention to "bony bridging in tuberculosis of the spine" The present authors agree that this is possible because they have found not infrequently quite extensive new bone formation in the repair of joint tuberculosis in cases in which there have been no communicating sinuses with secondary infection They have also noted that healing by the production of osseous tissue is more prevalent in tuberculosis of the vertebrae than in hip or sacro iliac involvement About 15 per cent of their cases of Pott's disease showed new bone formation during the healing stage The differential diagnosis from an *x* ray standpoint between tuberculous joints, arthritis deformans, and some cases of septic joint disease must occasionally lie in the appreciation of secondary findings, such as the presence of paravertebral abscess and the association of pulmonary tuberculosis

417 Operative Indications in Acute Mastoiditis

FOR the early diagnosis of mastoiditis, G LILBAULT (*Paris Méd*, September 6th, 1930, p 206) lays emphasis on three chief symptoms the pain, the temperature, and the discharge The signs formerly considered as characteristic occur too late, and only appear after the mastoiditis has become well established, with the risk of grave complications At its onset an acute otitis causes extremely sharp, lancinating pains, which, as a rule, subside when the tympanum is opened, either spontaneously or by paracentesis In other cases this amelioration does not occur, the pains, though less severe, persist and assume a neuralgic character Finally, in some cases the spontaneous pains disappear, but a careful palpation of the mastoid will provoke them at certain precise points Surgical intervention is not indicated when the pains are accompanied by a satisfactory general condition and by a progressive fall in the temperature, or when the pains persist for a few days with only slight fever This rule applies only to the first days of the otitis Should the pains persist for a longer period, with marked fever, antrotomy is indicated The temperature curve, obtained by morning and evening observations rather than a single isolated taking, should be the guide to operation Should this curve show a rising tendency, surgical measures are indicated, another operative indication is a sudden marked evening rise of temperature, even though there is a drop next morning Variations in the discharge are indicative of mastoid infection If the discharge continues to be abundant and is accompanied by pains and fever, antrotomy should be performed In some cases the discharge ceases abruptly, and if pain and fever are absent the infection may be considered as having ended If, however the mastoid becomes painful, and the temperature rises, the discharge is very probably being retained in the mastoid cells, and an operation should be performed without hesitation LILBAULT maintains that these three symptoms are of great value when considered together, a single one alone rarely suffices for diagnostic purposes

418 Surgical Treatment of Angina Pectoris

D DANIELOPOLU (*Zeit f klin Med*, Bd 113, 2 Heft, p 294) records 28 cases of angina pectoris in patients aged from 24 to 64 who had been treated in different countries (Rumania, America, France, Italy, Austria, and Spain) by suppression of the pressor reflex The operation consists in extirpation of the cervical sympathetic, leaving the stellate ganglion intact, this is associated with section of all the vertical branches of the vagus, the rami communicantes connecting the inferior cervical and first thoracic ganglion with the sixth, seventh, and eighth cervical, and first dorsal nerves, the vertebral nerve, and the nerves forming the anastomosis between the superior laryngeal nerve and the vagus These nerves do not contain any fibres, the section of which is dangerous, but they carry a sufficient number of centripetal cardio aortic fibres which require section to prevent anginal attacks In his previous publications Danielopolu had suggested that the operation should be carried out in two sittings, but as the result of his subsequent experience he recommends that the whole operation should be completed at once In the great majority of cases the operation was completely or almost completely successful The patients in whom the results were not so good were those in whom it was impossible to perform the complete operation The absence of any fatalities is attributed to the fact that care was taken to avoid cutting important nerves such as the inferior cardiac nerve, the stellate ganglion, and the rami communicantes connecting this ganglion with the second, third, and fourth dorsal nerves

419 Gastro-intestinal Lymphogranulomatosis

L SUSSIG (*Deut Zeit f Chir*, August, 1930, p 344), who has had three cases of solitary lymphogranuloma of the alimentary canal in a comparatively short period, believes that this condition is not so rare as it has been considered It is frequently diagnosed erroneously as tuberculosis, "lymphadenoid sarcoma," or carcinoma Sussig's first patient was a man, aged 41, with the tumour in the lesser curvature of the stomach The other patients (female) were aged 18 and 52 years respectively, and both tumours were situated in the ileum All the patients showed progressive emaciation, fluctuating temperature, and a yellowish skin with malar flush In all cases the Wassermann and diazo reactions were negative, and there was slight polymorphonuclear leucocytosis. The first patient had symptoms of gastric ulcer lasting six months, he was admitted with a temperature of 102 9° and signs of complete obstruction, and the diagnosis made was perforated gastric ulcer The temperature fell and the symptoms subsided Skiagrams showed a shadow as large as a date over the pancreas, there was rigidity of the stomach wall After a test meal the stomach contents were found to contain blood, hydrochloric and lactic acids were absent The patient returned to work, but was readmitted for an operation on the ulcer A hard tumour was found in the lesser curvature, as large as a pigeon's egg, the mesentery and mesocolon were thickened and contracted, and there was enlargement of the glands in the lesser omentum and around the pancreas and aorta The tumour appeared to be an inoperable carcinoma, it was adherent to the liver and pancreas, and the patient died two months later At the necropsy a crateriform ulcer was found to have penetrated the left lobe of the liver, causing abscess formation, the pus showed a mixed infection Histologically the growth proved to be a typical lymphogranuloma The second patient had had irregular periodic

abdominal pain localized for three months in the right iliac fossa A hard ill-defined nodular tumour extended from the symphysis to the umbilicus In view of a history of pulmonary tuberculosis conservative treatment was instituted, but complete obstruction with bilious vomiting necessitated laparotomy A large nodular tumour was found to be firmly adherent to the parietal peritoneum and bladder, which were studded with many small greyish nodules The upper pole of the tumour had perforated a loop of ileum, the adjacent mesentery was thickened and contained many enlarged lymph nodes The tumour, which completely filled the pelvis, was removed after resection of the bladder and the lowest coil of ileum with the thickened mesentery, followed by termino-lateral ileo-colostomy Paralytic ileus ensued two days later and the patient died on the seventh day Sections of the peritoneal nodules and of the tracheo-bronchial glands showed calcifying tubercles containing tubercle bacilli The third patient aged 52 had had pain in the right iliac fossa for two years, occurring four to six hours after food, and relieved by defaecation Four months before admission appendicectomy was performed without relief, the pain increased and was followed by bilious vomiting She was anaemic and emaciated, with slight pyrexia The abdomen was very distended and tense below the umbilicus; there was visible peristalsis and considerable polymorphonuclear leucocytosis Skiagrams showed stenosis or strangulation of the ileum At operation the lowest five inches of ileum was found to be very dilated and indurated with mesenteric thickening and enlarged glands, eight inches was resected with its mesentery The patient recovered The tumour was a typical lymphogranuloma, greyish homogeneous and non necrotic, there was no bacterial infection Sussig reviews the various etiological theories concerning lymphogranuloma (1) that it is due to protozoal infection by *Entamoeba histolytica* trichomonas, or chilomastix (2) that it results from a modified tuberculous infection, (3) that it is due to a corynebacterium and (4) that it is a disease *sui generis* of unknown origin Sussig claims that his cases were of definitely tuberculous origin, one being associated with the presence of diphtheroid bacilli, which reveals the mode of entry and primary infective focus Extirpation of the local lesion is necessary, followed by medicinal and x-ray treatment

Therapeutics

420 Dietary Therapy of Chronic Arthritis

WHILE most cases of chronic arthritis appear to be initiated either by infection, trauma or strain or by the menopause from a clinical standpoint it is apparent that many factors such as fatigue occupation metabolism, worry, diet and nutrition, contribute to the development of this condition A. A FLETCHER (*Journ Lab and Clin Med*, August 1930, p 1140) discusses these nutritional and dietetic factors A relationship is generally recognized between the digestive system and the development and course of chronic arthritis Some disturbance of this system such as constipation diarrhoea, or putrefaction may precede the onset of joint disease or parallel its severity, and relief of arthritic symptoms may be obtained by changes in diet and by colon irrigations Goldthwaite and others have directed attention to certain changes in the abdominal viscera visceroptosis, intestinal stasis, and bowel atony Fletcher believes that many factors particularly nutrition and diet, influence the tone and motility of the bowel McCarrison has shown that bowel atony and degeneration of the colonic mucosa in monkeys was produced by feeding autoclaved diets rich in carbohydrates The bowel changes in chronic arthritis are structurally and etiologically of the same nature, under the influence of a diet rich in vitamin but poor in carbohydrate the tone of the colon improves and it tends to regain its normal shape and contour Such a diet is outlined Therapy of this kind involves two general principles the liberal use of foods with high vitamin contents and the restriction of those constituents, such as carbohydrates which favour deficiency disease Treatment by diet should not exclude the use of other additional measures Recovery is likely to be slow, since the colon changes and long standing gastro-intestinal disturbances antedate the arthritis Patients with chronic arthritis are liable to develop focal infection, and this tendency is influenced by corrective dietetic measures Visceroptosis, intestinal stasis and atony are associated with faulty nutrition, and are improved or cured by a course of dietetic treatment Colon disturbances have been observed in cases of rheumatoid arthritis osteo-arthritis and menopausal arthritis, in all these conditions dietary measures have proved beneficial Fletcher maintains that faulty nutrition is the most frequent and most important basic factor in the development of arthritis.

421 Insulin in Delirium Tremens

K BENDIXEN (*Tidsskrift f d Norske Laegefor*, September 1st, 1930, p 940) was induced to treat delirium tremens with insulin by a publication in *Monatsschrift für Psychiatrie und Neurologie* (December, 1929) by E Klemperer who found that this form of delirium is associated with an incomplete dissolution of the alcohol molecule Intermediary products (acetaldehyde or by products thereof) are formed which are responsible in part at any rate, for the symptoms Insulin having been experimentally shown to hasten the dissolution of alcohol in the body, he argued that it would be beneficial in delirium tremens, the more so because insulin has already been shown to be of therapeutic value in certain diseases of the liver—an organ the functions of which are disturbed by alcohol poisoning On the basis of eighteen cases, Klemperer came to the conclusion that insulin treatment, conducted in a hospital, is without danger, and is superior to the usual fractional treatment with veronal, and Bendixen's cases, similarly dealt with, support these conclusions In one of them fractional treatment with veronal had first been tried, but without success In three cases treated by Bendixen the results were satisfactory, his dosage was a little higher than that recommended by Klemperer, who gives in the morning and at midday two subcutaneous injections of 8 to 10 international units with an interval of one hour between them Five units are administered in the evening if necessary Since the blood sugar curve runs more or less parallel with the pulse rate, careful observation of the latter and of the patient's general condition renders the physician relatively independent of blood sugar tests

422. Medicinal Treatment of Gastric and Duodenal Ulcer

W L PALMER (*Arch Int Med*, August, 1930 p 165) discusses the value of acid neutralization in the treatment of gastric and duodenal ulcers Apart from gastroscopy there is no means of determining when an ulcer has healed or of measuring the rate of healing, since an active ulcer may be present even when the radiographical signs and all traces of occult blood have disappeared The first stage of healing is the subsidence of the inflammatory reaction about the ulcer, as indicated by the rapid disappearance of spontaneous pain and the early transition from a positive to a negative acid test this may be taken as a rough index of the rate of healing Observations upon two groups of patients were conducted by Palmer in order to present data bearing upon the part played by free gastric acidity in the rate of healing of gastric and duodenal ulcers In the first the 'alkali group an attempt was made to neutralize the free acidity throughout the entire digestive period whereas in the second the 'beef tea group, gastric secretion was purposely stimulated in order to maintain as high a free acidity as possible By observing the rate of desensitization of the pain producing mechanism, conclusions were drawn as to the result in each group It was found that two-thirds of the 'beef tea group patients became free from spontaneous pain, indicating desensitization even without alkali therapy that neutralization of the gastric free acidity with alkalis definitely increased the rate of desensitization of the pain producing mechanism and that neutralization of the gastric free acidity favoured healing These experiments are held to indicate that desensitization of the pain producing mechanism occurred in both groups of patients and that the duration of the positive acid test definitely exceeded the duration of spontaneous pain in the 'alkali group, but only slightly in the beef tea group The hourly administration of beef tea did not stop the healing process but neutralization of the free acidity definitely favoured it

423 Treatment of Serum Sickness.

B SCHICK (*Kinderärzt Praxis* September 1930 p 12) emphasizes the importance of prophylaxis, and deprecates unnecessary injections of serum such as passive immunization of all the members of the family when one of them has contracted diphtheria or scarlet fever The growing tendency to inject all cases of scarlet fever with antitoxin is also held to be undesirable The toxin antitoxin mixtures employed in the United States have for several years contained goat or sheep serum instead of horse serum anatoxin contains no serum Some serums, such as tetanus pneumonia and scarlet fever antitoxins, are more likely to give rise to unpleasant symptoms than others, but the toxicity of the serum is diminished by precipitation of the pseudo globulin with ammonium sulphate or electrodialysis The rarity of fatal cases is shown by the fact that though Lamson has collected 41 examples from the literature Pfaundler had only 3 deaths among 1,000 000 injected and Park 1 among 50 000 The persons exposed to special risk may be divided in two groups asthmatic subjects especially those who are hyper sensitive to emanations from horses, and persons who have

had previous prophylactic or therapeutic injections of serum Before injection, therefore, in every case an inquiry should be made as to whether the patient is the subject of asthma or any other allergic disease such as hay fever or eczema or whether he has had any previous injections of serum for any purpose Sensitiveness for horse serum can and should be tested by diluting the antitoxin 1 in 10 with normal saline solution, and injecting 0 05 intracutaneously, especially before intravenous or intrathecal administrations of serum Desensitization should be secured by the subcutaneous injection of small quantities of serum The first dose should not exceed 0 01 c cm If no symptoms occur a double dose can be injected intravenously, and in another twenty minutes the dose can be redoubled, and so on If symptoms appear the following dose should not be doubled, but the same dose should be repeated in half an hour's time When intrathecal injections are needed the same method should be continued until the amount injected intravenously is 10 c cm In persons whose hypersensitiveness is low, especially with subcutaneous or intramuscular injection, the interval between the doses may be shortened and the size of the doses may be more than doubled A solution of 1 in 1,000 adrenaline should be at hand in every case where an injection is performed The ordinary methods for treatment of shock should also be employed

424 Opium Administration in Diabetes

R N CHOPRA and J P BOSE (*Indian Journ of Med Research*, July, 1930, p 15) systematically examined a series of hospital patients suffering from diabetes in order to test the accuracy of a belief prevalent in India that small doses of opium are beneficial in this disease The patients were kept strictly on the same diet for a few days before and after the period during which the drug was being tested When the daily output of sugar in the urine ran at a constant level the drug was given in gradually increasing doses, the excretion of sugar being carefully measured every day, and the blood sugar examined at regular intervals The psychological element was eliminated by masking the taste and smell of the opium with oil of citronella so that the patient had no idea of what drug was being employed The initial dose was 1 to 2 grains a day increasing by 1 grain every third or fourth day until from 6 to 8 grains were being taken daily, when the drug was stopped, either suddenly or gradually Some patients received as much as 10 to 12 grains each day without experiencing the least discomfort By these means it was found that the administration of small doses of opium (1 to 6 grains daily) slightly reduced the total urinary output in mild cases, but in serious cases there was no reduction in the polyuria, thirst, or frequency of micturition In early and mild cases opium has a well marked effect in reducing the total daily excretion of sugar in the urine, even causing complete disappearance in some instances, but in serious cases it had no effect on the sugar output The drug has but little effect in reducing the blood sugar, in severe forms of the disease it actually increases it The authors conclude that its use is inadvisable in diabetes, since in some patients the renal threshold for sugar excretion is raised thereby, while the sugar disappears from the urine the amount in the blood is increased

Neurology and Psychology.

425 Progressive Athetosis

SINCE the pioneer work of Kinnier Wilson and of C and O Vogt much has been learned concerning the function of the basal ganglia Several cases of progressive athetosis have been reported and evidence is accumulating that this distressing syndrome usually occurs when there is disease of the corpus striatum, perhaps particularly of the caudate nucleus B CROTHERS and S COBB (*New England Journ Med*, July 31st, 1930, p 213) record a further case in order to assist the accumulation of evidence A male infant was born some four weeks before term without difficulty, and nothing abnormal was noted until the age of 8 months, when he did not sit up When seen at the age of 13 months the child was under weight, nervous and showed athetoid, almost choreiform, movements About eleven months later the left side was more spastic than the right, no clonus was noted, and plantar stimulation produced athetosis rather than a typical Babinski response The impression then was that the child had a profound disturbance of motor control chiefly extrapyramidal, without serious mental defect The most probable cause was assumed to be haemorrhage occurring in the course of the premature labour Systematic muscular training was tried but three months later the child had acute otitis media Some months subsequently decided improvement had occurred However, at the age of 6 the child again became ill, and died on the eighth day of this illness the respiration suddenly ceasing after the development of marked retraction of the neck, dilatation of the pupils, and Cheyne Stokes breathing Post mortem examination of the brain showed morphological anomalies of the convolutions, which indicated that the brain was congenitally abnormal The lesions in the basal ganglia were very definite, and are best explained, according to the authors, as processes of repair following some former injury, this process had not stopped when the original damage was healed by absorption and scar formation, but had gone on as a progressive gliosis, which had gradually involved both the caudate and lenticular nuclei, and, to a less extent, the thalami In this case, again, the etiology was merely a matter of speculation, and the only possible diagnosis was gliosis of unknown origin The authors conclude that the changes in the nerve cells and glia of the cortex were probably acute, and due to terminal toxæmia, asphyxia, and circulatory changes, they do not consider them significant in relation to the principal symptom, the athetosis

426 Psychopathology of Ulcerative Colitis.

DURING psychological investigations in relation to disease, C D MURRAY (*Amer Journ Med Sci*, August, 1930, p 239) noted in a number of cases of ulcerative colitis that the personality of these patients gave many indications that deeper problems of psychopathology should be investigated Accordingly, a study was made of the life histories and mental attitudes of twelve patients suffering from ulcerative colitis, and these revealed a close association in time between the emergence of a difficult psychological situation and the onset of the intestinal symptoms Four cases are described in detail, these show a well marked time relationship between the outbreak of an emotional disturbance and the beginning of the disease It is well known that emotion is often accompanied by hypermotility or spasticity of the colon, and probably also by hypersecretion and vasomotor disturbances The exact mechanism of this phenomenon is unknown, but the reality of a nervous link between mental states and colon troubles is virtually proved by the many histories which reveal a close time relationship between the mental and physical symptoms An outstanding trait in colitis patients is their emotional immaturity, all the patients studied revealed definite childish elements in their character Mental conflicts concerned with marriage were more commonly found than other types of situations which might evoke anxiety In each case the patients faced their problems in an inadequate, infantile manner Murray believes that if the pathological process has not progressed too far, a thorough investigation into the patient's life and mentality is indicated and may afford opportunity for much needed psychotherapy

427 Tumours of the Occipital Lobe

I M ALLEN (*Brain*, July, 1930, p 194) reviews the clinical features of 40 cases of tumour of the occipital lobe, and discusses their frequency, pathogenesis, and significance In 24 of the cases the tumour was confined to that lobe, in 6 the posterior part of the temporal lobe, and in 10 a portion of the parietal lobe, were also involved The initial symptoms were epileptiform attacks in 30 per cent , a visual aura or visual hallucinations in 12 5 per cent , general mental impairment in 17 per cent , headache in 35 per cent , transient or progressive failure of vision in 15 per cent , and strabismus in 2 5 per cent In only 12 5 per cent did the initial symptoms suggest that the visual paths were involved The relative frequency of different symptoms was visual hallucinations, 25 per cent , abnormality of the visual fields, 16 per cent , epileptiform attacks, 52 5 per cent , auditory hallucinations, 5 per cent abnormal tastes and smells, 12 5 per cent , headache, 95 per cent , diplopia, 22 per cent , impairment of vision, 57 per cent , speech disturbances, 35 per cent , spontaneous subjective sensations, 30 per cent , disturbances of motor functions, 52 per cent , and mental symptoms, 55 per cent Important findings on examining the patients were mental changes, 60 per cent , contralateral homonymous defects of the visual fields, 94 per cent , papilloedema or optic atrophy, 70 per cent , inequality of the pupils, 35 per cent (larger contralateral pupil in 25 per cent), ocular paresis, usually of the external recti, 30 per cent , nystagmus and nystagmoid jerkings, 35 per cent , speech disturbances, 30 per cent (50 per cent of left sided tumours), sensation disturbances of the supra thalamic type, 55 per cent , and minor degrees of motor disturbance, usually in the contralateral limbs, 90 per cent The changes in the visual fields in the majority of cases occurred only in the contralateral halves of the field In individual cases the fields showed complete hemianopia up to the fixation point Incomplete hemianopsia with spacing of the field for central vision, quadrantic defects, peripheral crescentic defects, and no abnormal changes When vision was failing a concentric contraction of the fields was

also sometimes found Focal symptoms and signs were limited to unformed visual hallucinations and distortions of the visual fields Symptoms and signs referable to a definite neighbourhood were important in localization, and with the exception of speech disturbances, were probably the result of oedema or vascular changes near the tumour or of pressure on adjacent structures, sometimes intensified by raised supratentorial pressure Symptoms due to increased pressure in some cases were confusing and enhanced the risk of erroneous localization In most cases symptoms of increased intracranial pressure predominated from the beginning in a few instances epileptiform attacks occurred for some time in others there was a history of exacerbations of increased intracranial pressure for as long as two years

Obstetrics and Gynaecology.

428. Etiology of Puerperal Sepsis.

IN an attempt to determine the actual source of infections arising during the puerperium JOHN TAYLOR and H D WRIGHT (*Journ Obstet and Gynaecol of the British Empire* Summer No, 1930 p 213) report the following findings In the vagina in 1 123 women *immediately before delivery* were found non haemolytic haemolytic pseudo-haemolytic and anaerobic streptococci in 37 8 2 7, 1 3 and 1 1 percentages respectively Pseudo-haemolytic strains, producing no haemolysis in serum broth but definite haemolysis on the plate, were present in 22 patients of whom 20 subsequently had an afebrile puerperium, one had mild sepsis due to another organism, and one had pyelitis Of 32 patients harbouring true haemolytic streptococci, 29 had an absolutely apyrexial puerperium of the other three one had staphylococcal mastitis and in another instance a sore throat and fever developed on the fifteenth day *Of thirteen women in whose vaginas anaerobic streptococci* were found three later developed fever, but none from infection with an anaerobic streptococcus. It would appear, therefore, that streptococci present in the vagina before delivery do not usually produce infection After *delivery, on the third day, streptococci* were present in the vaginal flora in slightly increased proportions, especially was this the case with anaerobic streptococci but clinical evidence of infection was absent in patients having these bacteria in the uterus or vagina *In respect of cases of puerperal morbidity (as defined by the B M A standard) the* authors found that of 125 cases 50 were certainly and 27 others probably due to an extrauterine cause Of the remaining 47 definitely septic cases 14 were caused by haemolytic streptococci 10 by anaerobic cocci and 8 by *B coli* In none of the fourteen septic cases in which haemolytic streptococci were obtained did death ensue and only about half were of moderate severity of the five (hospital) cases in which ante natal bacteriological examination had been made, none had then shown the presence of haemolytic streptococci It *appears that the bacteria present in the vagina before* delivery are a less serious danger than those entering during or after labour Stress is laid on the importance of anaerobic organisms and the relative infrequency of haemolytic streptococci A prognosis based on bacteriological findings alone is said to be almost invariably deceptive

429. Treatment of Leucorrhoea.

L ADLER (*Wien Klin Woch*, July 28th 1930 p 948) remarks that to determine the correct line of treatment in leucorrhoea the origin of the discharge must be ascertained and its etiology be defined It must be remembered that a copious non inflammatory discharge may cause secondary inflammation lower down *Gonorrhoea is not so common as is* supposed and should be excluded by microscopical examination *Vulvo-vestibular discharge is usually a sequel of a* descending infection it often becomes infected and is accompanied by burning and irritability Hyperidrosis and abnormalities of the urine must be dealt with if present before local treatment can be of any use benefit may then follow tepid bathing and powdering during the day *If the condition* is acute rest in bed with hot fomentations is required If it is chronic, painting with a silver solution will clear it up *Vulvo-vaginitis of little girls* may be due to gonorrhoea masturbation, oxyuris infestation, or cystitis treatment follows the same lines, with 10 per cent silver nitrate application in obstinate cases. Of vaginal discharges the non inflammatory as seen in young girls is due to constitutional causes True vaginitis may be exogenous due to infection from without or trauma it is more often endogenous, however and attributable to ovarian hypofunction and constitutional anomalies Attention to the general health is the first line of treatment, associated with organotherapy to stimulate the ovaries For any form of vaginitis local treatment is necessary If properly performed, douching gives good results in severe inflammation, a 0 5 per cent solution of mercury oxycyanate should be instilled through a tubular speculum followed by vaginal lavage with a silver preparation If the condition is acute this is employed daily, otherwise every second or third day with a douche of weak camomile tea in between *This routine treatment is often* sufficient but individual idiosyncrasies may have to be considered Dry dusting does not give good results Tampons and pessaries of various medicaments may be very useful in cases where douching is making the mucous membrane too dry In cases where the discharge originates from the cervix gonorrhoea has been over-emphasized and the possibilities of erosion, ectropion and damage from contraceptive pessaries have been underestimated Local treatment with corrosives can only be carried out in the absence of inflammation after swabbing with alkalis silver nitrate or protargol should be applied The corrosive used should be applied again in about four days time, and the treatment be repeated at least five or six times Tears and erosions require operative treatment Such local measures may also be used in hypersecretion due to psychic causes or ovarian action The body of the uterus seldom causes discharge, but it may appear in glandular hyperplasia or polyposis, when curetting is necessary Pus is found only in severe inflammation and pyometra If carcinoma can be excluded, dilatation of the cervix and douching will cure it

430. Haematometra with Utero intestinal Fistula.

A V VIKOULOF (*Gynecol et Obstet* June 1930 p 500) reports the successful treatment on conservative lines of a case of cervical atresia with haematometra in which the uterus communicated with the small intestine A married woman aged 27, who had never menstruated had suffered for twelve years from monthly attacks of pain latterly accompanied by vertigo and transient amblyopia melaena had been constantly present for twelve months The uterus was greatly enlarged, but did not admit the sound for more than 5 cm Diseased and adherent uterine appendages were removed on both sides a fistula of the width of a goose quill connecting the fundus of the uterus with the small intestine was excised and ventro-fixation was performed seventeen days later the uterus was drained by the forcible introduction of a sound through the cervix Six weeks subsequently the track which had closed was dilated During the ensuing twelve months regular and painless menstruations became established and melaena has ceased

431. Pregnancy and Parkinsonism

P BROOKE BLAND and L GOLDSTEIN (*Journ Amer Med Assoc* August 16th, 1930 p 473) who record an illustrative case with a review of the literature, come to the following conclusions. Chronic epidemic encephalitis does not render a woman sterile and the incidence of abortions in patients who conceive is about the same as in other women Pregnant women are not specially susceptible to the infection of epidemic encephalitis *Clinically the disease pursues much* the same course in the pregnant as in the non pregnant woman although the mortality rate is somewhat higher Pregnancy may aggravate latent or quiescent encephalitis in patients who have previously suffered from the disease Women who contract acute encephalitis in pregnancy are especially liable to develop Parkinsonism the incidence being from 75 to 80 per cent as compared with 25 per cent in non pregnant women Except in a small proportion of cases chronic encephalitis does not have an unfavourable influence on pregnancy and labour On the other hand pregnancy has a decidedly unfavourable effect on Parkinsonism La thy although encephalitis may be transmitted to the foetus such transmission is exceedingly rare

432. Pregnancy after Hemihysterectomy

ACCORDING to P PETIT DUTAILLIS (*La Gynecol* June 1930 p 350) a double uterus of whatever variety is as well adapted in one of the halves as an ordinary uterus for the function of reproduction provided that that half is sufficiently developed and free from acquired disease. In confirmation he describes the case of a patient operated on for pain chiefly menstrual due to iliac ectopia of the obliterated right cornu of a pseudo-didelphic uterus with the corresponding adnexa. The ectopic organs were removed together with the fibrous band which united them to the other half of the uterus. The second patient a girl aged 18 had had left hemihysterectomy for acute symptoms due to torsion of the left horn of a bicornuate unicervical uterus with left haematosalpinx and intraligamentary haematoma after subsequent marriage two healthy children were born in successive labours at term In the first pregnancy also pregnancy proceeding to term followed operation

Pathology.

433 Physiological Properties of Insulin

In a brief review of certain physiological properties of insulin C H Best (*Canad an Med Assoc Journ*, August, 1930, p 141) states that, although it has not been established that mammalian tissues other than the pancreas cannot produce small amounts of insulin there is no doubt that the insulin concentration in the pancreas is greater than in any other organ The insulin found in various tissues is probably transported by the blood from the pancreas Without doubt some insulin can be obtained from the tissues of severely diabetic animals and of patients dying in diabetic coma As one of the mechanisms responsible for the liberation of insulin from the pancreas of normal animals is operating in the diabetic—namely, the increased sugar concentration of the blood—this insulin should be considered as active One action of insulin in normal and diabetic animals is the formation of muscle glycogen from dextrose It is reasonable to suppose that the reduced amounts of insulin in diabetes are promoting the formation of muscle glycogen, but are not adequate for the prevention of excessive sugar formation, the accummulation of the ketone bodies, and other abnormalities which may cause death There is satisfactory evidence that the islands of Langerhans produce the pancreatic insulin which leaves this organ in the venous blood Stimulation of the right vagus, fibres from which may be traced to the islet cells, produces a lowering of the blood sugar figure Glucose concentration of the blood is the chief agent in controlling the liberation of insulin from the pancreas, and the nervous mechanism is of secondary importance Among the effects of insulin are decrease of nitrogen excretion, the rapid diminution of the ketone body concentration in the blood, rapid fall of the blood phosphorus content, diminution of the excess urinary phosphates, and a definite increase in muscle glycogen Some investigators believe that the glycogen formation and dextrose combustion account for practically all the sugar which disappears when insulin is given, others believe that a decrease in sugar from protein and fat must also be brought about Many factors reduce the efficiency of insulin—namely, interference with glycogen formation in the liver and muscles, bacterial infections, anaesthetics, and diets Best concludes with a few remarks on the preparation of insulin—and the relation between insulin administration and diabetic mortality

434 Immunization in Syphilis

M Truffi (*Ann de Derm et de Syph*, July, 1930, p 689) concludes that as regards mankind there is no natural immunity to syphilis, and that many species of animals hitherto considered refractory are only apparently immune In a syphilitic subject reinoculation lesions correspond generally to the symptoms of the particular stage of the original disease, except that spirochaetes inoculated into the skin cannot penetrate without first producing a local lesion Apparently partial immunity begins to develop from the commencement of the primary incubation period, during the pre secondary stage a gradually increasing degree of immunity is observed A fresh inoculation lesion originates as an initial syphiloma, but later becomes papular, the incubation being usually short and abortive Immunity increases during the period of generalized symptoms During the latent period immunity decreases slowly, deeper re inoculation lesions and signs of distal diffusion may occur During the tertiary stage the skin reacts strongly to the introduction of a fresh virus, and immunity diminishes more rapidly In general paralysis the skin is almost entirely refractory to reinoculation, this refractory state is less evident in tabes Congenital syphilis produces no immunity to fresh infections No absolute proof can be shown that a given syphilitic patient can be considered cured, nor is it possible to differentiate superinfection and reinfection Neither in man nor in animals has it been possible to distinguish differing strains of spirochaetes with affinities for certain organs Although allergy is an expression of immunity, exact agreement between these two states cannot always be demonstrated in syphilis The immunizing substances are probably of histogenetic rather than humoral origin, but their nature and mode of action cannot be demonstrated, neither can it be explained why the disease at a given period tends to be confined to a single system, organ, or part of an organ In syphilis there is no true immunity, but only an immunity by infection, as such it is not transmissible, except with the infection itself Intensive early treatment destroys immunity, probably because it destroys infection, such a result is rare in the more advanced period of the disease

435 The Haematology of Peruvian Wart

C Monge and P Weiss (*Rev Sud Amer de Méd et de Chir*, June, 1930, p 570) describe from observations on eighteen cases the characteristic appearances of the blood in Peruvian wart (Carrion's disease), a Bartonella infection The severe rapidly developing anaemia of this disease has the megaloblastic and megalocytic characters of pernicious anaemia There is a fall of the red cell count to about one million per c mm, with the appearance in the circulation of all forms of red cells from the most undifferentiated type to the adult erythrocyte, and much basophilia, polychromatophilia, poikilocytosis, and anisocytosis This condition is associated with a leucocytosis up to 20,000 per c mm of a leukaemic granulopolynuclear type, reflecting the granulocytic activity of the bone marrow There is a marked nuclear deviation to the left with predominance of young, immature forms, such as metamyelocytes, myelocytes, and myeloblasts with azure granules, Turck cells and plasma cells are generally present, and also immature forms of the lymphoid series, which can be differentiated by the oxydase reaction There are also many primitive monocytes, including the primitive parenchymatous forms usually met with in leukaemia Generally the condition may be regarded as a leukanaemia The authors find that the earliest sign of haemotological remission is the onset of a monocytosis, when the parasites (Bartonella) leave the red cells to pass into the tissues This remission is accompanied by a rise in the number of the red cells, a diminution in the number of immature forms, and disappearance of megalocytosis In favourable cases the remission is followed by a gradual return to a normal blood picture

436 Opsonin and Bacteriotropin Actions

M Strumia, S Mudd, Emily B H Mudd, B Lucke, and M McCutchfon (*Journ Exper Med*, September 1st, 1930, p 299) have previously reported that serums which have promoted the phagocytosis of acid fast bacteria have regularly produced certain alterations in the bacterial surfaces in corresponding degree They now record the results of a study undertaken to determine the distribution of the substances responsible for the surface and tropin effects in the several fractions of immune serums Antiserums against several strains of acid fast bacteria were separated into their euglobulin, pseudoglobulin, and albumin fractions The globulin fractions were found to possess the essential properties of bacteriotropic serums, thus they alter the bacterial surface properties, and, in quantitative correspondence, cause agglutination and phagocytosis, these several effects withstand washing of the sensitized bacteria, and are little, if at all, affected by inactivation of the antiserums before fractionation, the combination of antibody and antigen is serologically specific It is concluded that the contact of antigen with fresh homologous immune serum results in the deposit on the antigen surface of a substance, or substances, contained in the globulin fractions of the antiserum, as a consequence of this surface deposit the leucocytes can spread over and engulf the antigen The same investigators (*ibid*, p 313) also report the results of further tests of tropin action These indicate that precipitation, agglutination, the surface changes, and increased phagocytosis are all consequences of one underlying phenomenon—the specific chemical combination with and deposit on the surface of the antigen of antibody protein The several serological reactions then follow as consequences of the properties of the sensitized surface and of the special environing conditions The antibody is contained in the globulin fractions of immune serum, and appears to be a globulin with chemico physical differences from normal serum globulin

437 The Sedimentation Test in Acute Anterior Poliomyelitis

R Huss (*Nordisk Medicinsk Tidskrift*, August 30th, 1930, p 517) has observed the rate of sedimentation of the erythrocytes in 62 cases of acute anterior poliomyelitis treated in the fever hospital in Stockholm The cases were classified according as they were, or were not, characterized by paralysis, but there was practically no difference between the sedimentation curves in the two classes No correlation could be established between the rate of sedimentation and the height and course of the fever, nor could any relationship be established between the sedimentation and the leucocyte curves The first conformed to the type characteristic of the large group of acute infectious diseases in which the rate of sedimentation is only slightly increased Sudden changes in the curve, such as have been observed in scarlatina and recurrent fever, were never found, nor did injections of serum increase the rate of sedimentation, as is sometimes the case in serum treatment of other diseases.

ASPIRIN DERIVATIVES

IN

RHEUMATISM, NEURALGIA, AND INFLUENZA

"ASPRIODINE"

A compound of Aspirin and Iodine

CONTAINING 41·47% IODINE FOR RHEUMATIC AFFECTIONS AND ARTERIO SCLEROSIS

Bots of 25 5 grain Tablets 2/6 100 7/6

"SEDASPRIN"

A compound of Aspirin and Bromine

CONTAINING 30·86% BROMINE FOR INSOMNIA AND NERVE AFFECTIONS

Bots. of 25 5-grain Tablets 2/6 100 7/6.

"PHENYL-ASPRIODINE"

AN INTESTINAL AND URINARY ANTI SEPTIC. EMBODIES THE ACTIVITIES OF IODINE, ASPIRIN AND PHENOL

Bots of 25 5 grain Tablets 2/6

"PHENYL-SEDASPRIN"

A NEW COMPOUND OF THE SALOL TYPE EMBODYING THE EFFECTS OF BROMINE ASPIRIN AND PHENOL

Bots. of 25 5 grain Tablets 2/6.

"METHYL-ASPRIODINE"

THE NEW ANTI RHEUMATIC FOR INUNCTION

BALM 3/ LINIMENT 3/-.

"MAGISAL," "TYLCALSIN," and "TYLLITHIN"

ARE VALUABLE SOLUBLE SALTS OF ASPIRIN WHICH ARE PROMPT IN ACTION AS ANTI NEURALGICS AND ANTI RHEUMATICS

Original Bots. of Tablets 2/- and 7/6

Samples of any of the above supplied on request

Write also for particulars of Peptone, Mercurome, and other Martindale preparations

W. MARTINDALE

12 NEW CAVENDISH ST, LONDON, W 1

Telephone Langham 2440 *Telegrams "Martindale, Chemist London"*

"Knowledge of the properties of SUGAR of MILK essential to all responsible for infant welfare"

"THE striking fact that the tremendous decline in infantile mortality in New Zealand of 31 per thousand in twenty-five years has been coincident with the increasing use of sugar of milk, which has risen from noth ng twenty-five years ago to 313,600 lb per annum today, makes a more complete knowledge of its properties essential to all responsible for infant welfare," a London doctor writes

Humanized milk (cow's milk diluted, to which is added up to 5½% of lactose) is already freely prescribed by doctors in this country, but hitherto the difficulty of obtaining satisfactory sugar of milk at a reasonable price has tended to postpone the universal adoption of this method of feeding

With Serolac brand sugar of milk costing only 1/5½ per lb, humanized milk is both a more satisfactory and a much less expensive substitute for breast feeding than the average prepared baby food

Full particulars as to sources of supply, etc, may be obtained from Whey Products Limited, Haslington, near Crewe — manufacturers of Serolac brand of sugar of milk

"HOMMEL'S HAEMATOGEN"

A natural organic TONIC associated with nourishing albuminous proteids.

AN EFFICACIOUS REMEDY IN ALL FORMS OF ANAEMIA

associated with constitutional diseases

Obtainable in Syrup *and* Tablets

"SEDIN"

Nervinum-Sedativum

Consisting of

Pot Brom	0·4	gramme	(grains 6½ approx)
Sod „	0·4	„	(grains 6½ approx)
Ammon „	0·2	„	(grains 3 approx)
Salt „	0·1	„	

combined with Vegetable Extract in form of soup tablets (A disguised dietetic form)

Samples free and carriage paid on application to—

HOMMEL'S HAEMATOGEN & DRUG CO., 121, Norwood Road, Herne Hill, London, S.E.2

STANIFORM

Regd. BRAND Trade Mark

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns scalds, etc

DUSTING POWDER
For application where a greasy substance is counter indicated

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis

LOTION
A panacea for Mosquito and other insect bites Most effective for all purposes where Tr Iodine is employed Does not stain the skin and there is no sting

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use

Supplies may be obtained through the Wholesale Druggists, Druggists Sundriesmen, or Dental Supply Companies

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men

'I have treated with Staniform' a very bad scald of chest in a child who had boiling water spilt over her It healed completely in fourteen days without a scar

I have tried Staniform' in the Out patients Department and both Nursing Staff and myself were amazed at results obtained Long standing, non healing skin wounds healed after few applications

'This is to certify that Staniform' has been used with great success in the Emma Klinick (Utrecht, Holland), in cases of bed sores, in burns of heat and X rays

Similar testimony has been received from a large number of medical men when Staniform has been used for the treatment of Burns, Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals

STANIFORM over a wide field of clinical experience has exhibited positive curative properties Combining the well known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing

STANIFORM LTD, CARNWATH ROAD, LONDON, S W 6

Priced at 3/- and 3/8 per lb

A super quality at 4/2 per lb

DOCTOR'S CHINA TEA

FOR ALL CASES OF GASTRIC TROUBLE

It is definitely not safe to allow any tea but China tea to be used when there is the slightest tendency to gastric trouble The Doctor's China Tea has no excess of Tannin whatever—it is a really good blend of China tea—it is therefore ideal as a delicious and healthful drink for all who enjoy a good cup of tea and especially for those of your patients who suffer from any form of indigestion

"We are much impressed with the value and usefulness of Medinal'" —— M D

SCHERING LTD, 3, Lloyd's Avenue, London, E C 3

Infantile Diarrhoea.

A letter recently received.

The Medical Adviser of
Messrs Kaylene Ltd,
London

Dear Sir,

The case to which I referred was a child of six months who was brought to me after having treatment elsewhere for diarrhoea and vomiting The child was practically a skeleton and apparently had been vomiting everything—even medicines—for many days The mother thought, and her friends thought, the child was dying, and I happened to be the nearest doctor I gave the child one teaspoonful of plain Kaylene in plain, cold, boiled water, and kept the mother and child in my consulting room to watch effects If ever a child was drawn from the jaws of death, I think that little sufferer was The Kaylene was retained, the gasping steadily lessened, the haunting look of that child's eyes became less distressing, in fact, the change for the better was so pronounced that in an hour's time I allowed the mother to take the child home

Fortunately, I had sufficient Kaylene by me (a sample you kindly sent), and I gave the mother sufficient to give a teaspoonful every hour during the night The chemists' shops were all shut by this time I gave full instructions—strict instructions—not to give anything else but Kaylene and plain, cold, boiled water as I had done

In the morning the mother came to see me and informed me that only twice during the night the child had loose stools but no vomiting, and had slept fairly well The child had other two loose motions during the day, but not offensive ones like all the other stools In the evening the child cried—the first time for two days—and as she looked, and was, so much better, I gave her some white of egg with plain, cold, boiled water Still improving, I kept her on this for three days She was doing well and I then allowed her milk She made a complete recovery, and there can be no doubt whatever that Kaylene saved the child's life

Yours faithfully,

..... MB, CM

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

1 It is individually fitted to suit the case
2 It is simple and true to tone, and leaves the hands free
3 It removes strain, thus relieving head noises, giving inconspicuous hearing
4 It conveys sounds from varying ranges and angles
5 It is entirely different, unexplained, and carries a guarantee and service system
6. It is suitable for "hard of hearing" or acutely deaf through various causes
7 It is helpful for conversation, music, in church, wireless, home, office, public work, and sports

FREE HOME TESTS
arranged for Doctors and Patients
Medical Prescriptions made up to the minutest detail

MEDICAL REPORTS
Commended by all leading medical journals—Mr Dent will be happy to send full particulars and reprints on request

"ARDENTE" STETHOSCOPE.
Mr R H Dent makes a Stethoscope specially for members of the medical profession suffering from deafness Many are in use and excellent results are reported on the latest as evidenced by the interest shown at the last B M A Meeting

Woollen Underwear is Healthiest

If the case for woollen underwear had been an old wives' tale, wool would have died as unlamented as tight-lacing corsets

But people know that winter woollens are still good sense

Apart from its warmth and comfort, scientific investigation* has shown wool to be very absorbent, and more important still, to retain better than any other material the moisture it has absorbed It therefore protects against sudden chills and the discomfort due to condensation of moisture on the skin

Where rheumatism is feared, woollen underwear allows free perspiration without the danger of constant damp

Wolsey pure wool underwear is as good a woollen underwear as there is It is both soft and hard-wearing, unshrinkable, and is made in a widely accommodating range of styles

WOLSEY

underwear

for Women, Men and Children

*Details of the investigation made by the British Research Association for Wool will gladly be sent to any medical practitioner on application to Wolsey Limited, Leicester.

WHOOPING COUGH

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible The food should be easily digestible, nourishing, and given a little at frequent intervals

There are no specifics for this disease In very young children drugs are administered with difficulty and are of uncertain effect

Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications and hasten convalescence

Treasurer SIR LIONEL FACDEL PHILLIPS Bart
Physician-Sup J G PORTER PHILLIPS M.D F.R.C.P

This Registered Hospital is now situated at Monks Orchard in some 250 acres of park pleasure and farm grounds and is ready to receive patients Application can now be considered on behalf of patients of the educated classes in a presumably curable condition With a view to early treatment voluntary or uncertified patients are admitted.

Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise The Committee will also consider applications for admission at lower rates and in certain cases will be prepared to admit patients free of charge.

Every facility for specialised investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X ray and Dental Departments and the Bio-Chemical, Pathological and Psychological Laboratories

Furthermore provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms

In addition to the Resident Medical Staff Consultants in special branches of Medicine and Surgery are available wherever required

The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms

For forms and further particulars apply to the Physician Superintendent at the Hospital

SUCCESSES WITH ACTINOTHERAPY . . .

Latest reports of its application . . . .

An outstanding roborant in rickets, debility, anaemia, many forms of tuberculosis, etc.

AS a general tonic treatment, as a specific in rickets and as a curative means in certain forms of tuberculosis anæmia, etc—actinotherapy is regarded as a most valuable addition to the armoury of present day medicine by an ever increasing number of the most highly qualified men Difficulty however, is often experienced in obtaining up-to-date information of the latest developments in this field—facts and figures relating to recent successes in this country and elsewhere

It is not unnatural that the Hanovia Company who have specialised exclusively in the manufacture of actinotherapy equipment for over 25 years and have supplied over 167 000 Quartz Lamps for medical purposes in all parts of the world should possess a most complete record of all such progress

In the Hanovia Company you have a clearing house, an authoritative collection of all available facts ready to supply your needs if you are interested in or practising actinotherapy

From whatever point of view you may be interested, Hanovia can supply you with the fullest information You place yourself under no obligation whatever by writing to the address below stating what special branch of work is most likely to interest you

WRITE TODAY FOR DETAILS OF THE HANOVIA REPRINT SERVICE

Hanovia data is divided under the following heads —General Practice General Surgery, Public Health Work Tuberculosis Pediatrics Dermatology Gynæcology Oto Laryngology etc. etc Over one hundred reprints of these and other subjects are available for free distribution to the Medical Profession A full list of these will be sent to you together with copies under any heading of special interest to you Write for this list to day Mark the enquiry Dept. 9

Advertising Helps the Reader

Readers of the Journal are presented week by week with a comprehensive summary of products necessary to the medical man both in his professional and private life The advertisement pages of the Journal are carefully scrutinised before going to press, in order that our readers may deal confidently with those firms whose announcements win their interest and attention

Modern advertising seeks to increase demand, thereby stimulating production and building a circle of prosperity, which ultimately reacts to the advantage of the purchaser himself Advertised products necessarily maintain a high standard of excellence, for disaster must naturally come speedily to the manufacturer who through any cause and at any time loses the confidence of his customers

It is the policy of the Journal to convince advertisers that doctors prefer to be approached directly through the pages of their own publication, for in this way we believe manufacturers are encouraged to consider the special needs of the profession, and to study closely the results of their efforts to meet these requirements when seeking orders from medical men

The "small" advertisements section provides a *forum* for the "domestic" business of the profession, and those wishing to arrange the Sale or Purchase of Practices, requiring Assistants or Assistancies, and Partners or Partnerships, may in these pages reach thousands of their fellow medical men at very economical cost Such transactions may, in addition, be protected by the secrecy which the free Box Number service provides

Clinical Evidence

The value of Radiostoleum—a potent concentrate of Vitamin A and Vitamin D—as a prophylactic and therapeutic agent for use in combating divers infections depends largely upon its content of Vitamin A the vitamin which possesses remarkable power to build up resistance

As far back as June 1929 two well-known clinicians demonstrated that Radiostoleum possessed this power even to the extent of overcoming sepsis when infection had supervened (B M J 1st June 1929 p 984)

The findings of these workers have been confirmed in regular clinical practice and there is now ample evidence that in cases of lowered resistance generally with consequent susceptibility to prevailing infections Radiostoleum is a vitalising agent of unique value.

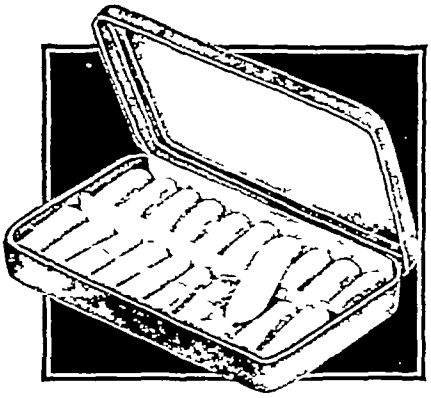
REINFORCED COD LIVER OIL —BOOTS



THE therapeutic value of Cod Liver Oil is fully appreciated by the Medical Profession It is recognised for its specific action (due to its high content of Vitamins A and D) in rickets, affections of the chest, and diseases arising out of malnutrition Boots Reinforced Cod Liver Oil is a biologically controlled preparation containing five times the amount of Vitamin D in addition to the normal amount of Vitamin A The advantage of a concentrated oil needing only a fifth of the usual dose will be particularly valuable Four fluid ounces of Reinforced Cod Liver Oil —Boots, contain the same amount of Vitamin D as one pint of the finest Norwegian oil

In 4-oz bottles, 2/6.

A *New* chemo-therapeutical preparation

for the treatment of influenza, septic diseases and toxemias

Used in Amazon for treating Influenza for the past three years with great success. The physician's sample illustrated here will be sent to you free on request

DISULPHAMIN is chemically ortho-oxybenzoyl-sulphon-nucleino-formol sodium tetradimethyl-amino-antipyrin-bicamphorated

The antitoxic action is based on the assumption that Disulphamin transforms the toxic colloid to a crystalloid thereby facilitating its dialysis through the walls of the blood vessels and accelerating its elimination by the kidneys.

While phenol is bactericidal in a 1/100 dilution Disulphamin is bactericidal in a dilution of 1/10 000 to 1/50 000

In a series of tests made in the treatment of Influenza with Disulphamin it was found that the course of the disease was materially shortened, and very seldom did Broncho-pneumonia or other complications supervene Although the etiology of influenza has not yet been clearly determined it appears that Disulphamin exerts a polyvalent action

The clinical results thus far obtained are so encouraging that physicians have ample justification for employing Disulphamin in Febrile Toxemias arising from Sepsis.

Samples and literature including charts of actual tests and important hospital findings will be sent free on request to Messrs. COATES & COOPER, 41 Great Tower Street, London E.C.3

DISULPHAMIN

Product of
THE BIO-CHEMICAL LABORATORIES
LOCARNO, SWITZERLAND

Lactose 73%
Dextrin 25%

. . . *in palatable combination*

Lactose 73%, dextrin 25%—that is the proportion in which these carbohydrates are combined in this new food for changing the intestinal flora Both are more slowly absorbed than other carbohydrates, and both are able to reach the colon in sufficient quantity to cause a luxuriant growth of protective flora An acid reaction of the intestinal contents unfavourable to toxic organisms is thus produced —Lacto-Dextrin being highly efficient in promoting the growth and development of both B acidophilus and B bifidus in the colon In this pure carbohydrate food both lactose and dextrin are presented in a palatable and agreeable combination

PSYLLA

. . an accessory for use in conjunction with Lacto-Dextrin

Where bulk and lubrication of the intestinal tract is also required, the use of BATTLE CREEK Psyllia (Plantago Psyllium) is invaluable as an accessory The small brown seed when in contact with water swells into a soft gelatinous mass and acts most effectively both as an emollient and intestinal evacuant.

Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper 41 Gt Tower St London E.C.3 Sole Distributing Agents for the United Kingdom and Irish Free State.

LACTO-DEXTRIN

Manufactured by the BATTLE CREEK FOOD CO., Mich., U.S.A.

Mellin's Food
A MILK MODIFIER

MELLIN'S FOOD is specially prepared for modifying and adjusting cow's milk to meet the nutritive needs of infants deprived of human milk

No matter whether certified, pasteurised, dried, or condensed milk is employed, its digestibility and its value as nourishment for the baby is enhanced by the addition of Mellin's Food In other words, milk in any form is better borne, more completely utilised, and its nutritive constituents more appropriately balanced if properly modified with Mellin's Food

There is no milk modifier exactly like Mellin's Food, and its continued recommendation by a large number of members of the Medical Profession is ample evidence of its outstanding advantages

Further particulars and samples will be supplied on request

"MODIFIED MILK IN INFANT FEEDING"

The above-named booklet of 64 pages will be gladly sent to members of the Medical Profession

MELLIN'S FOOD LTD., LONDON, S.E.15

MEDULLA RUBRA

BONE-MARROW IN ANAEMIA FROM HAEMORRHAGE

W Borchardt (*Deut med Woch*, March 28th 1930 p 521) records the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood In the first series some of the animals were fed with rib marrow others with marrow from the long bones Control animals received a corresponding amount either of fat or of liver extract The basal diet in each case contained a sufficiency of iron (5 mg per cent) Only the animals receiving the rib marrow showed a definite increase of weight and their haemoglobin formation was more rapid than that of the others. In the next series the experiment was repeated, but the iron content of the diet was reduced to 1 4 mg per cent The result was similar but more striking the dogs receiving the rib marrow regaining their haemoglobin far more quickly than the others

THIS extract from the "Epitome of Literature," published in the "BRITISH MEDICAL JOURNAL," dated May 3rd last, is important as representing, in 1930, a complete justification of the formula upon which

Roboleine
THE FOOD THAT BUILDS THE BODY

has been produced without variation during the past twenty-five years

The success of ROBOLEINE is thus due to intelligent anticipation and to consistently maintaining the highest possible standard of manufacture

Medical Practitioners are asked to satisfy themselves of the merits of ROBOLEINE, for which purpose testing samples will be gladly sent upon request

AETHER PURISS. B.D.H.

"I have found it very satisfactory in every way The period of induction was remarkably easy for the patient, and there was no post-anaesthetic sickness"
—, — —, M D

Aether Puriss B D H is made from pure rectified spirit and is subjected to an elaborate process of chemical purification which is followed by delicate analytical tests

Aether Puriss B D H is therefore perfectly pure when made and is packed in such a manner that its original purity is in no way jeopardised.

The special manufacturing process and the method of packing preclude any possibility of the formation of peroxides aldehydes or other harmful oxidation products which might produce undesirable post-operative effects

The purity stability and reliability of Aether Puriss B D H are appreciated universally by anaesthetists

MONSOL in *MIDWIFERY*

Monsol Liquid Germicide 1/ &2/

Monsol Internal Capsules 5/

Monsol Dental Cream 1/-

Monsol Ointment 1/3&2/

Monsol Medicated Soap 8d.

Monsol Throat Pastilles 1/3&2/3

Monsol Pessaries 4/

An authority on the subject has expressed the considered opinion that the use of Monsol in midwifery would reduce the incidence of Puerperal Sepsis by fully 90 per cent

Bacteriologists and Clinicians have proved repeatedly that Monsol has a selective action on Streptococci—an action ten times greater than lysol (which cannot destroy these germs except at a concentration liable to injure the tissues)

Monsol is the product of a Mond Laboratory prepared under strict scientific control

Outstanding features of Monsol are

1 A high germicidal power against the organisms that cause sepsis
2. A bland and emollient action—non irritating to the tissues and mucous membranes at therapeutic concentrations
3 Low toxicity (One-sixth as poisonous as lysol)
4 Great powers of penetration reaching deep-seated inflammation

Many Hospitals Nursing Homes and Lying in Institutions are now specifying the use of Monsol in all maternity cases In addition to reducing the risk of infection Monsol leaves the hands and skin soft and supple a fact much appreciated by the Nursing Profession.

Invaluable as a Galactagogue

This nourishing and sustaining food drink is helpful to nursing or expectant mothers

NOT only hundreds, but literally thousands of cases are recorded in which this well-known preparation — Horlick's Malted Milk — has proved its efficiency as a body-building food

It is particularly valuable as an addition to the diet of the expectant and nursing mother For Horlick's is a perfectly balanced food containing fat, proteins and soluble carbohydrates combined together in correct nutritive ratio It is prepared from fresh, full-cream cows' milk, selected wheat and malted barley — and, during manufacture, is partially predigested to ensure easy assimilation

Horlick's is rich in valuable malt-sugars, but contains neither cane sugar nor free starch It is therefore extremely easily digested, and highly productive of energy

These characteristics make it valuable as a galactagogue Its abundant nutriment supplements any deficiencies in the mother's regular diet, and promotes a regular and nourishing supply of milk, and its easy digestibility makes it acceptable when other forms of nourishment are unwelcome

Taken during pregnancy, it builds up the mother and helps to maintain her vitality A cupful taken regularly first thing in the morning frequently abolishes and almost invariably alleviates the discomfort of morning sickness

Horlick's is now obtainable in two forms — the original, natural-flavoured Malted Milk, and the new Chocolate Flavoured form — identical in its constituents with the original Horlick's, but flavoured with fine chocolate Horlick's is sold in sealed glass bottles, price 2/-, 3/6, 8/6, 15/- Also in tablet form

Further details may be obtained from Horlick's Malted Milk Co, Ltd, Slough, Bucks

HOW GIBBS HELPS THE DOCTOR

Gibbs takes the Oral Hygiene Message into the British Family Circle

A great deal of good would be done if every Doctor in Great Britain could find time to have a talk with all his patients at very regular intervals upon dental matters An impossible task—and, happily, not altogether necessary Gibbs nation-wide advertising and their intensive educational work is doing far more for each Doctor's charges than he could possibly do himself

At least once a week—often every day—in some homes, almost every hour—some message about dental hygiene is delivered by Gibbs in every family circle in Great Britain

Always it is just such a message as the Doctor himself would give if he could be there in person—a reminder to clean teeth regularly—a warning to see the Dentist at the least sign of anything being wrong—a word as to the importance of right diet in making good teeth and keeping them sound —a hint that once at least in six months a dental examination is very desirable

Every stratum of society is reached—men, women and children are told how—with the help of the Dentist—they can be sure of perfect teeth all their lives

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates, Bridgework (both gold and vulcanite) and artificial teeth It gives a high polish, removes stains makes plate or teeth sterile and antiseptic without in any way injuring the softest gold or the finest vulcanite or platinum The formula has been submitted to and approved by important members of the Medical Profession

The Original Preparation
English Trade Mark No 276477 (1905)

Local Anæsthesia in Surgical Practice

OPERATION ON NECK AND REMOVAL OF TESTICLE.

Typical Case

S J , male, aged 72 years

Diagnosis (1) Tuberculous cervical adenitis (2) Tuberculous epididymitis and orchitis (right side)

Operation (1) Block dissection of neck (2) Right orchidectomy

Anaesthesia 77 c c of 0 5 per cent Novocain-Adrenaline solution

Operation An infiltration block of the ilio-inguinal and ilio-hypogastric nerves, and as the cord was exposed it was thoroughly infiltrated The pudic nerves were blocked, and the tuberculous testicle and epididymis were removed The patient was allowed to leave the hospital in a few days, and he returned on March 3rd, 1920, at which time he had a complete dissection of the right side of his neck, using 120 c c 0 5 per cent Novocain-Adrenaline solution

—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr)

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work published by Henry Kimpton, 263 High Holborn, London, W C 1)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act

Vitamin foods and physiological balance

THE influence of food upon the maintenance of health is in direct relation to the manner in which the various essential food factors are present in correct physiological balance. No one of these food factors alone, however essential in itself, can bring about the complete physical development that Virol does For in Virol the various Vitamin foods are in properly balanced proportion with the all important mineral salts, and are blended into a delicate and palatable emulsion, that is immediat ly acceptable and easily assimilated—even in the most delicate conditions

No other food gives the same results, for no other food contains all the ingredients of Virol in the same scientifically balanced proportions.

In the treatment of

GENITO-URINARY DISEASES

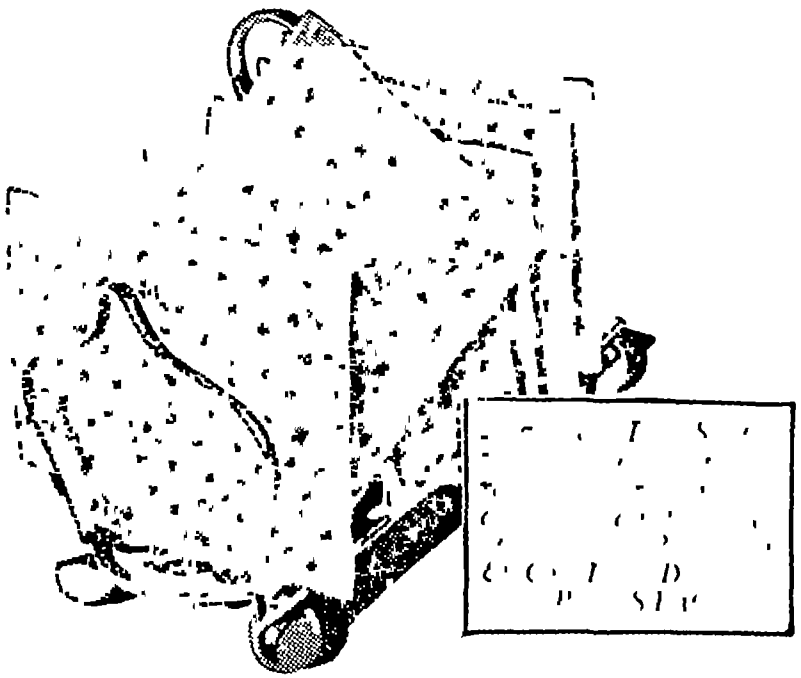
including

cystitis, pyelitis
cervicitis, prostatitis, epididymitis
gonorrhoea, vaginitis, etc.

Pyridium displays strong anti-bacterial properties toward coccal bacteria and B Coli It is of special service therefore in mixed infections and owing to its capacity for concentration in the tissues and organs of the genito urinary system its beneficial effects are noted in addition to Cystitis and Pyelitis in such conditions as Prostatitis Epididymitis Vaginitis Urethritis Endometritis etc

TRADE **PYRIDIUM** MARK

[Phenyl azo alpha alpha diamino pyridine hydrochloride]



Pyridium is administered orally in the form of 0 1 gram tablets—2 t i d —and in its early excretion through the urine which it colours orange to red it exercises a soothing and healing effect on the mucous membranes Pyridium has marked power of penetration which explains its success in counteracting the ravages of cocci and bacilli below the surface and it also stimulates the proliferation of epithelial cells It is characterised by its freedom from toxic effects and its employment is not contra-indicated in pregnancy

For the guidance of medical practitioners we have prepared a series of leaflets giving the technique of Pyridium treatment in various indications Any or all of the following will be gladly sent on request —

(1) CYSTITIS and PYELITIS (2) CERVICITIS ENDOMETRITIS SALPINGITIS PYOSALPINX. OVARITIS etc. (3) EPIDIDYMITIS and PROSTATITIS (4) GONORRHOEA (Urethritis Vaginitis and Arthritis) (5) CHANCROID

Pyridium is the registered trade mark of the Pyridium Corporation of New York

Menley & James Ltd , P.O Box 12a, Hatton Garden, London

Health Aspects of Vita-Weat

In cases of diet regime a readily acceptable and beneficial alternative to ordinary bread will be found in Vita-Weat—the whole-wheat British crispbread

The "Lancet's" Report.

Being made from 100% stone-ground whole wheat, Vita-Weat preserves all the vitamins intact The *Lancet* reports that Vita-Weat is "a valuable foodstuff, more particularly in respect of its content of Vitamin B" Vita-Weat is also rich in Vitamins A and D, in proteins, and in the valuable mineral salts so necessary to health

Extremely Palatable

Vita-Weat is extremely palatable, possessing a delicious "crunchiness" and ripe-corn flavour Its crispness encourages mastication and so promotes a healthy condition of the teeth and gums

High Calorie Value

"The calorie value of Vita-Weat," says the *Practitioner*, "is 2,132 per lb, which may be compared with the calorie value of fresh white bread, namely 1,210 per lb" It will thus be seen that Vita-Weat possesses a high physiological fuel value

To Counteract Constipation.

The branny scales of Vita-Weat act as a stimulant to normal peristalsis, whilst not exerting an undue irritative effect on the intestinal mucous membrane

To Prevent Obesity.

The starch granules in Vita-Weat are thoroughly disintegrated No starch passes unconverted into the body to cause obesity and indigestion Vita-Weat is "completely assimilable," states a report of the Royal Institute of Public Health

PLURIGLANDULAR DISPENSING

The choice of pluriglandular formulae for the various conditions in which organo-therapy is indicated is often difficult. There may be a considerable difference of opinion as to dosage, and physicians may from their practical experience decide something quite definite, but which is probably not in accordance with the usual formulæ.

The growing and varied needs of the profession in this respect are well catered for in our Organo-therapeutic Dispensary. A complete range of Gland substances is always in stock and prescriptions can be promptly and accurately dispensed.

THYMUS CO.

This is one of our recognized formulæ. It is put up in Tablets and in Elixir form, each dose representing Thymus sicc. gr. 2, Thyroid sicc. gr. ½, Whole Pituitary sicc. gr. $\frac{1}{10}$. It is suggested for the treatment of marasmic conditions and atrophy. In addition it may be employed in dealing with nutritional disorders and defective development of bony or other tissues. Full particulars of this and other formulæ will be found in our brochure "PLURIGLANDULAR FUNCTION," which may be had on application to

EVANS SONS LESCHER & WEBB Ltd.

LIVERPOOL 56 Hanover St. DUBLIN LONDON 50 Bartholomew Close

Tonsillitis in all its Forms

TONSILLITIS and particularly Follicular Tonsillitis is often stubborn and unyielding, with a great tendency to developing into the suppurative form

When it becomes apparent that suppuration is inevitable, the application of hot poultices is an old and accepted treatment.

Due to its thermogenetic potency and to its bacteriostatic action

Antiphlogistine

induces an active hyperaemia in the affected area, which dilates and flushes the superficial capillaries, stimulates leucocytosis, and promotes the destruction of the bacteria.

Antiphlogistine has the advantage of being unfermentable and bacteriostatic, and will cling around the contour of the neck, when other applications are difficult to retain in place

An Address
ON THE
PSYCHOLOGY AND PSYCHOPATHOLOGY OF CHILDHOOD *

BY
R. D. GILLESPIE, M.D.,
PHYSICIAN AND LECTURER IN PSYCHOLOGICAL MEDICINE, GUY'S HOSPITAL

EVERYONE knows that the last decade of medical work and thought has been characterized by nothing more than by an increasing appreciation of the importance of psychological factors in the production of ill health. This rediscovery has been derived primarily from the study of adult ill health, but one of its fundamental implications is that adult psychological disorders depend very often and very largely upon conditions personal and environmental, which have existed in childhood. In childhood itself the share of psychological factors is probably even greater than in adult life in producing illness, for the child's entire psychophysical system is more labile than the adult's, and emotional disturbances lead more readily to bodily effects. Moreover, in children, disturbances of a psychotic kind are absolutely rare, and the mental disturbances which do occur have usually a closer and more obvious connexion with immediate factors than is encountered in most adult disorders, no matter of what general clinical type.

There are consequently several principal directions of interest for the student of child psychopathology. These are the psychopathology of childhood for its own sake, the physical signs and symptoms produced by emotional factors and especially prone to occur in children, and the connexion of adolescent and adult psychological morbidity with childhood and its influences. The first and especially the second of these directions are of peculiar interest to the student and teacher of paediatrics, for a numerically important and varied group of physical disturbances of a fairly distinctive kind results from emotional and temperamental influences. The third is one which interests the professed psychiatrist more, but the paediatrician who explores it can make valuable contributions in a largely unworked field of preventive medicine.

General Fallacy of Interpretation

One caution must always be observed. It is a caution of interpretation. We must be careful not to play the Lewis Carroll or the Kenneth Graham, measuring what we observe in a child's mind too much in terms of adult knowledge and experience. It may seem superfluous to issue such a caution to those who are brought face to face with a similar situation in treating the physical illnesses of children, but in psychological affairs we are far more apt to interpret what we see not merely in terms of adult experience in general, but of our own in particular. Not to do so is difficult even for those who remember better than the majority their own childhood; indeed this remembering may itself be a source of bias, experiences that are similar to our own being too readily attributed to similar causes. There are other errors of interpretation of which I shall speak later.

PRINCIPAL CHARACTERISTICS OF CHILD PSYCHOPATHOLOGY

There are three cardinal points for discussion in the psychology of children considered apart from the psychology of adults, as far as distinctions in this field can be drawn. They are first the great influence of environment upon the child's mental processes, secondly the plasticity of the latter, and thirdly the prominence of egoistic tendencies, their substitution and frustration in the production of symptoms. Environment means, of course, the personal environment of parents, brothers, sisters, teachers, and companions, and an important reflection occurs here that when signs of morbidity appear they arise at the surface of contact, so to speak, of the child's environment with his aims and desires, rather than at some locus of conflict deeply within the psyche. It is far more often a question of some direct frustation than of a conflict between an introjected ideal and libidinous unconscious wishes.

Influence on Method

This is a generalization which admits exceptions, but it is of sufficient importance in theory and especially in practice, to warrant expansive discussion. For instance, it connotes that relatively simple adjustments of the environment, after careful consideration of the tendencies whose frustration or misdirection are indicated by the symptoms, will cause the latter to disappear, and that intensive intrapsychic exploration of the child's mind is usually unnecessary. Hence the psychiatrist's method of exploring the problem principally through interviews, with parents and other adults more than with the child himself, has its justification. There is, however, a small residue of cases in which intensive exploration may be desirable.

Prognostic Contrast in Children and Adults

The second point, the plasticity of the attitude and behaviour of children, is another aspect of the first, and is of immense practical and theoretical importance, although this plasticity is limited in some degree by inborn disposition and temperament. Taking the most superficial aspect of the whole problem first, we are confronted by such a contrast as this, which shows the recovery rates in a group of adults and in a number of children who attended the out-patient practice of the department of nervous disease and psychological medicine in Guy's Hospital two years ago.

The statistical analysis of 70 adult patients who were treated at that time and have subsequently been followed up gives this result:

Not traced	7
Dead, committed suicide, or disappeared	9
Condition little changed	28
Improved	14
Much improved or cured	12
Total	70

This gives a percentage of 37 improved or cured. A similar investigation among 60 children two years after their treatment gives the following figures:

Not traced	5
Condition little changed	16
Improved	15
Much improved	24
Total	60

This gives a percentage of "improved" or "well" of 65. The groups are statistically very small, but the figures are sufficiently in accord with general impressions to be considered reliable. One has the more confidence in the figures for the group of children, because it included all varieties, even such unfavourable ones as feeble-minded and epileptic children.

Controls

The improvement all round was so marked and so invariable, where it could be expected, that the reflection readily arises that so-called "nervous" children would usually get better of themselves without the aid, sometimes nowadays very elaborate, of the clinic. Indeed, while giving proper weight to the immense effect of the child's environment in producing psychological disturbances, it is necessary to remember that all children are subjected to innumerable traumata, and the wonder is not how many nervous or unstable children there are, but what a large proportion grow to be reasonably normal men and women. The urge to adaptation has been well styled imperative. Nevertheless, the comparatively few unstable ones are in the aggregate many, and their contribution to adult social inefficiency and ill-health is sufficient to make psychiatric work with children not only as worth while as any, but worth extending till every considerable hospital has the necessary facilities and has intimate connexions with other social organizations for child welfare, as well as with children's courts.

* Given to the International Paediatric Congress, Stockholm, August 1930.

Role of Innate Factors

Just as too much optimism may lead to a policy of *laissez-faire* on the ground of the self-adjustment of the majority of psychopathological phenomena in children, so on the other hand may a pessimism, preconceived on the score of the importance and immutability of inborn temperament and disposition, lead to a failure to grasp numerous possibilities of modification, for the limitations produced by inborn factors are much less than is generally supposed. It is a sound working rule to attribute nothing morbid whether of behaviour, mood, or thought, to congenital and therefore presumably less modifiable causes until a complete investigation has exhibited nothing in the history of environmental influences and personal events that will reasonably account for the symptoms, and until the latter have been proved but little modifiable by any known therapy, and even then the matter may not have been congenitally engraved.

Prophylaxis of Adult Neuroses and Psychoses

The practical importance of the plasticity of the child's mind in both its congenital and acquired aspects lies not only in the management of nervous children, but in the prevention of neurotic and psychotic disorders in later life. There are two principal views of the etiology of adult mental illness. Both of them place the primary focus in the formative influences of childhood, but one view regards the adult illness as the cumulative result of mental habits acquired and engrained throughout childhood and adolescence, while the other regards it as a regression to particular emotional "fixations" or attachments of an erotic kind at the same period. The apparent divergence of view lies perhaps more in emphasis and terminology, but they certainly agree in acknowledging the importance of early factors. It seems to me, however, that in its insistence on a set pattern, the Oedipus pattern in the infantile foundation of neuroses, the second view does less justice than the first to the almost infinite plasticity of the young organism's mental and emotional equipment, the wide variety of the influences that impinge upon it, and the multiplicity of its responses.

Self-assertive Tendencies and Their Handling

The third generalization, that symptoms in children centre principally round their egoistic, self-preservative or self-assertive strivings, is derived from a study of the nature of the symptoms, their mode of production, and their therapeutic reactions. The point, although it must seem obvious to many, is worth making, for the alternative view invokes the same explanation for children's nervous disturbances that is so commonly advanced for those of adults—namely, the vital importance of infantile sexuality. My impression is that in children the origin of psychogenic symptoms in the greater number of cases is, properly speaking, neither infantile nor sexual. No one now denies the existence of infantile and childish sexual desires. But two fallacies seem to be committed by exponents of the more rigorously Freudian view. To say that infantile sexuality exists is an entirely different assertion from the statement that it lies at the root of all neurotic disorders of children and adults. The other assertion is that infantile sexuality is the same as adult sexuality in its aims and objects. This is a type of assertion that is hard to disprove, for a negative finding is no proof to the contrary. Careful observation by ordinary methods in younger children fails to furnish as a rule evidence of sexuality of this type at the foundation of their functional nervous disturbances, the special methods which have been employed to show it, from contemporary studies of children (not from retrospective accounts from adults) do not command confidence as valid scientific evidence. I am thinking of Little Hans and some of the other psycho-analytic work with children. It is possible, of course, by a sufficient complication of hypotheses, to regard egoistic tendencies as themselves libidinous. A child's desire for praise, possessions, and other outlets of self-assertion may be said to represent libido which has been diverted to egoistic ends, but it is more useful as well as simpler to regard these tendencies for what they certainly are. There is an field of research here. Direct observation, unbiassed by esoteric pre-conceptions, is badly wanted. In the meantime, it is a safe working rule to regard the majority of children's psychogenic disturbances as disturbances of their egoistic strivings.

DISORDERS OF CHILDHOOD

A general survey of the varieties of mental and functional nervous disorders of childhood will illuminate the generalizations which have been made. (The age range given in several of the groups is that of children attending Guy's Hospital as out-patients in the last four years. Patients over 14 years of age are not included.)

1 *Disorders of Personality*.—Timidity, obstinacy, irritability, outbursts of temper, sensitiveness, shyness, day-dreaming, lack of sociability, emotional disturbances, etc. (Age range in the Guy's series 12 to 14. Intelligence quotient 81 to 103.)

2 *Behaviour Disorders*.—Truancy, wandering, temper outbursts lying, stealing, begging, cruelty, sex misdemeanours, food fads, refusal of food, etc. (Age range in the Guy's series 4 to 14. Intelligence quotient 67 to 103.)

3 *Habit Disorders*.—Nail biting, thumb sucking, incontinence—nocturnal and diurnal—constipation, vomiting, stammering, etc. (Age range up to 14. Intelligence quotient 77 to 127.)

4 *Psychoneuroses*.—Anxiety psychoneuroses (age range 7 to 14), hysteria (age range 5 to 14, intelligence quotient 64 to 93), phobias, obsessions, compulsions, ties (some).

5 *Psychoses*.—Schizophrenia (dementia praecox), manic depressive psychoses, etc.

6 *Epilepsy*.

7 *Mental Deficiency*.—Dull and backward group the result of general or localized defect—*for example, word* blindness and word-deafness, feeble-mindedness imbecility, idiocy, temperamental defect ("moral imbecility").

8 *Sleep Disorders*.—Insomnia, night terrors, somnambulism.

9 *Mental Disorders* occurring with, and probably dependent on, some physical disease—for example, chorea, epidemic encephalitis, trauma.

10 *Disorder of the So-called "Glycopenic" Variety*.—Migraine, crises of collapse, insomnia, night terrors, cyclical vomiting, etc.

This classification is proposed from experience as a convenient one, although it mingles symptomatic and diagnostic categories to some extent, and although there is also some overlap between the various subdivisions. The deviations of personality issue in abnormalities of behaviour but of a less *outspoken*, less impulsive, and more consistent type than those of subdivision 2. Habit disorders are distinguished from behaviour disorders in so far as they involve only a part of the child's behaviour—that is are a much simpler form of activity, and do not require conscious co-operation for their production. On the other hand some of them probably begin in no other way than as hysterical symptoms and deserve to be classified accordingly. This would hold especially for some instances of vomiting, of incontinence, and of constipation. Mental deficiency, especially in its lesser degree of intellectual subnormality, naturally interpenetrates the other groups. The *extent* is suggested by the results of systematic testing of every child who comes to a psychiatric out-patient department. Figures were compiled for fifty-two unselected children who attended as out-patients in the department of psychological medicine at Guy's Hospital during the first months of this year. A frequency curve exhibited well that the majority of the fifty cases of which detailed records were available had an intelligence quotient between 70 and 90—that is belonged to the "dull and backward" group, on this test. The figures suggested what would be suspected on general grounds, that an intellectual equipment less than the average does tend even at an early age, *to produce* additional difficulties in social adaptation, and to foster symptoms in a disproportionate percentage of the dull and backward. It occurred to me that the Binet-Simon tests might not do justice to these children. Accordingly performance tests were also given. Contrary to expectation, the results with performance tests

were inferior to those with the Binet-Simon scale, when compared with normal standards The general results were suggestive rather than conclusive The group was too small, and some other experience of the prognostic value of such tests for social adaptation after the school age has been passed makes me a little sceptical of their value in general My impression is that many of the so-called dull and backward who show abnormalities of behaviour and other symptoms of adaptive disharmony during the school age, often do remarkably well by comparison after leaving school This impression is borne out statistically by some figures recently supplied to R G Gordon from school children at Bath It seems, nevertheless, to be of great importance that a machinery for occupational guidance should exist which would begin to operate at the age of 12 This would go far to prevent much adolescent unhappiness, inefficiency, and nervous illness

To return to the clinical classification already given, the first two clinical groups and the fourth are the most important for establishing our general propositions regarding environment, plasticity and egocentricity It is convenient, however, to deal first of all with the other clinical groups, in summary fashion, but sufficiently to place them in their proper perspective, and to indicate openings for research

Habit Disorders

Some of the so-called habit disorders such as nail biting thumb sucking, and the like, belong to a group of which some variant occurs in practically every child (Olsen) Their *raison d'etre* is either pleasurable stimulation of the auto-erotic variety, or the non specific expression of a disturbed mental state Incontinence, although often similar in origin to these has a more varied etiology In our series at Guy's Hospital urinary and especially faecal incontinence has been most frequently associated with some degree of mental defect and on this and other grounds (especially the evidences of parental inadequacy) it is presumably often the simple result of lack of educational influences or capability But incontinence can also be present as the result of mental conflict, as the non specific expression of an emotional disturbance or more directly as a self-assertive phenomenon and sometimes as an erotic one As a symptom urinary incontinence can be cured by all kinds of methods, and all kinds of methods can fail Fear is said to be a frequent cause of it, but I have known additional fear to cause it to cease Urinary incontinence especially the nocturnal form is a problem not yet wholly solved, either in theory or in therapy

Psychoses Fallacies of Interpretation

With regard to Group 5, psychoses in the adult sense are so rare in childhood as to furnish relatively little material for psychological investigation It is important to remember that many traits which would be psychotic in an adult cannot be so regarded in a child In some recent literature there is a tendency to interpret the behaviour and thought of certain children in the same terms as would be used if the patient were an adult This is often fallacious and disregards the basis of a fundamental conception—namely, that of regression Certain forms of behaviour normal in a child if persisted in till adult life, would make the adult a psychotic and regression consists not in persistence in but in return to such behaviour—that is, it implies the reappearance of early traits in a late setting but there has to be a certain depth of regression before these traits are regarded as psychotic It is therefore not correct to say that simply because certain childish traits such as suggestibility and negativism, are highly accentuated in a child these traits betoken a psychosis The case is similar with certain kinds of mental content A child may believe itself a kind of god and yet not be considered to have a delusion in the adult sense for such ideas are common to many, and perhaps in a sense to all children at some time or another and differ only in the length of time for which they persist Most children feel omnipotence in some fashion at some time and hanker after it when they cease to feel it Often the more intelligent child disbelieves for a time the reality of anything but himself The tendency is to characterize such beliefs as psychotic only when they are expressed, and to ignore the fact that they are always present *in some form at some time*, although often not even consciously formulated except in the intellectually brighter children

This matter of *conscious formulation* is important and touches not only the interpretation of so-called psychotic traits in children, but the general psychotherapeutic accessibility of psychological disturbances in them In the degree of awareness of his mental processes and in his ability to observe and to express them verbally, the child is inferior even to the average adult In children we often feel that in the grave disorders of behaviour, the concrete reaction appears first, and the conscious formulation only afterwards, if at all Not only is this one of the reasons why it is unwise to conclude that certain symptoms that are prima facie psychotic are necessarily so, but it is also part of the reason why disorders of behaviour and even the more habitual deviations of personality are usually so readily altered in children There is little organized mental superstructure, conscious or otherwise of the reactions The external conditions are there and the reaction takes place let the external stimuli be removed, and the reaction dies out It is not merely that the hypothetical 'paths" are not deeply graven, but that there are no well-organized sets of motives no complex intrapsychic elaborations which will act to maintain and stereotype the abnormal reaction The whole process is more closely analogous to a conditioned reflex than one meets anywhere in the behaviour of adults and their mental disorders

The term psychotic is not, therefore, properly applied to such disturbances in children, but in so far as the term "regressive" can be truly applied, it can entitle behaviour or thinking to be labelled psychotic, and the latter term is thus sometimes applicable This conception, as has been pointed out also necessitates a certain "depth" of regression and the depth is a misnomer for a time sequence there is obviously less scope for manifestations of regression in children Nevertheless, these manifestations frequently occur but more often in the field of behaviour and in simple form, such as crying and babytalk than in the domain of thought When the regression include much of the child's thinking as well as his behaviour the temptation to think in terms of adult psychoses is stronger than ever, but it is more correct as well as safer not to be tempted to apply diagnostic terms borrowed from adult psychiatry to such instances The rule should be here, as always, to deal directly with the facts of observation and to avoid obscuring them with diagnostic terms, such as chizophrenia, unless their use in a given instance is unimpeachable

For example I recently saw a child, aged 6 whose condition had been diagnosed schizophrenic For the past eighteen months he had used only inarticulate sounds and cries He was very restless and distractible If presented with a book he turned over the pages rapidly in the manner of a child aged 2. Given a piece of paper, he scribbled at first wavy lines then when some simple diagrams were placed before him he produced crude geometrical forms He was not at all hostile or even apathetic for he placed his arm round the doctor's neck and his cheek against his, smiling slightly His entire behaviour, in fact, re-embled that of a child aged about 18 months or less It was certainly not schizophrenia and it lacked the push and infectiousness of a manic reaction Yet it was a much clearer instance of regressive behaviour than is usually found in adult mental disorder It seems better to state the facts in such a case and to leave schizophrenia aside

The conclusion is that when we say that psychoses are rare in children we are in a periphrastic way saying that the conditions are so different that as a rule the term psychosis as used in psychiatry generally is misleading

Glycogenic Disorders

The disorders belonging to the last three groups of our classification are very common and of great interest Many of the instances of disturbance of sleep are suitably considered along with the cyclical vomiting group Night

terrors, for example, and some cases of insomnia, are immediately dependent on the same general cause, and all of them are on that borderland of the psychological and physical which is of such fascinating importance, and for which the illnesses of children offer an unrivalled opportunity for study (cf chronic epidemic encephalitis) The problem in the cyclical vomiting group should interest the paediatrician who is not also a professed psychologist, since the symptoms are usually the direct expression of environmental stimuli, and do not as a rule involve the intermediary operation of psychic "complexes" It is now well established by observation—and I can confirm it amply from my own experience—that not only cyclical vomiting and its varieties, anticipatory and otherwise, but night terrors, certain headaches, often of migrainous type, some cases of collapse, some insomnias, certain cases of enuresis, and many cases of fatigue, belong to a group with the same metabolic fault behind them (Osman adds certain cases of constipation, pallor, anorexia, failure to put on weight, growing pains, pyrexia, recurrent diarrhoea, asthma, and cough) Since it was found that the administration of glucose acted like a charm in these conditions (Cameron), the metabolic fault was originally called "glycopenia," and it was shown by Swedish workers that while these symptoms were apt to arise in emotionally unstable children of asthenic physical type, many of them could be produced in normal children by cutting down the carbohydrate intake But curiously, it has now been shown by Osman that there is in fact usually no hypoglycaemia in children afflicted in these ways, and that what is found is an acidosis in the sense of a diminished plasma bicarbonate In the majority there is also no ketosis Osman suggests that glucose works because it builds up the glycogen reserve of the liver The relationship between nervous constitution and symptoms is in any case a close one, and represents in simple form a general problem which has always interested psychiatrists Here in children are the first beginnings of a biochemical description of constitutional characteristics, but the description is proximate and not by any means final Presumably in emotionally unstable children adrenaline is more readily secreted, and the glycogen reserves are more often subject to mobilization, so that the danger point for the production of symptoms is more readily and more often reached than in stable children

Disorders of Personality

The group of children whom I have classified as exhibiting abnormal traits of personality are of very special importance from a social and a prophylactic, as well as from a human, point of view There are also important theoretical considerations It is now well established that many instances of mental disorder in adults present an antecedent history of peculiarities of personal make-up—often simply accentuations here and there of traits that otherwise pass for normal I have pointed out that one school of psychiatric thought considers that mental disorder develops directly out of such traits, as a kind of cumulative resultant of their operation, after what might be termed a break in the psychic compensation that enabled an appearance of normality to be maintained for so long Now if these traits can be modified while they are still in the plastic stage which is so characteristic of childhood, or, still better, if they can be prevented altogether from forming, a great work will be done, as far as adult mental disorders are concerned, and much human unhappiness and inefficiency will have been prevented

It is an undoubted fact that many such morbific traits appear in childhood, and it is also a fact of observation that in childhood such or similar characteristics are modifiable Whether the modifiable and the morbific characteristics are precisely the same remains to be seen, but some who have worked with children on these principles are already inclined to believe that what would become some day adult psychoses are being prevented For example, Professor Hans Maier of Zurich, in whose asylum there is a cottage for psychopathic children, tells me he believes that something is being done there towards the prevention of schizophrenias

It is most important theoretically that the formation of a child's personal traits should be carefully scrutinized At present some psychopathologists are somewhat obsessed by what might be called the prototypic hypothesis—that is, that a mental attitude or characteristic is explainable most completely, or even solely, in terms of the conditions of its first (supposed) occurrence This would do less harm, were it not also assumed that the first occurrence must stand in relation to infantile orificial erotism Obstinacy, to take one character trait as an example, is explained in terms of anal erotism and reaction between the latter and environmental conventions But it is surely a matter of everyday observation that such traits can be formed and lost again in reaction to later desires and later influences

All these questions form material for study at first hand, to control or replace psychopathological data at present derived solely from the retrospective statements of adults This is a task for the psychologically minded paediatrician which will bring great rewards, both theoretical and practical In particular he will be struck by the plasticity of even the most ominous-looking personal characteristics, when compared with their rigidity in adults He will also be impressed by the rapidity with which environmental influences produce and modify these characteristics, and if he observes them in an objective way, without schematical preconceptions, he will probably find a dominance of ego tendencies, in so far as the inner contribution of the patient is concerned Even the clearly affective attachments are often more reasonably construed in terms of desire for self-assertion and of self-esteem than of erotic drives

Behaviour Disorders

The behaviour disorders are, for the most part, the manifestations of healthy self-assertive tendencies which have been frustrated This becomes evident both from an inspection of their nature and from analysis of the motives in individual instances The cases in which the disorder of behaviour indicates the frustration of some erotic goal in the narrow sense are comparatively rare Much more readily than the personality disorders, they yield to environmental rearrangement, in conjunction with brief talks with the child, sometimes of a mildly hortatory kind The social history of children of this group often bears an impressive resemblance to the history of juvenile delinquents There is a suggestive field for co-operative research here

Psychoneuroses

The psychoneurotic anxiety states and the hysterias of children indicate in my experience much the same conclusion, with an especially direct demonstration of the effects of environmental imitation and suggestion While we must be wary of using superficial and easy-going explanations, on the other hand a facile interpretation in more recondite terms is to be guarded against, as is illustrated in the following case

A boy, aged 11, was brought for advice because he was afraid of the dark He would not sleep in any room alone at home he was often peevish, and did not get on well with his younger brother, aged 8, who was a rollicking boy and physically stronger The patient was said to be very much attached to his mother The latter claimed to be able to intuit his thoughts, yet she appeared to have no knowledge of the details of the boy's fears and indeed knew virtually nothing of his inner concerns A skilled psychopathologist who saw the boy said it seemed to be on first scrutiny a very obvious Oedipus position, but that of course he could not commit himself without further knowledge His caution proved to be well justified, for on further inquiry the mother revealed that the boy had never been allowed to sleep alone and that he had slept for years in the same room with her, and always with a light burning The reason was that his mother hated marital intercourse, and dreaded having more children, and so kept the patient and the light near her as measures of protection She made no secret of the fact that she was mortally afraid of the dark In the circumstances it was therefore not very wonderful that her son was afraid of the dark and of sleeping alone An insistence on a more hygienic regime produced a remission of the boy's fears for a month when the mother, being no longer able to stand the anxiety induced by his deportation, took him back to her bedroom, with consequent relapse of the boy's condition

This was an unusually flagrant instance of the possibilities of misinterpretation, but it shows what is evident in many instances of anxiety in children—namely, the immense influence of parental example (often direct

example of obvious anxiety). The anxious atmosphere surrounding the child becomes the natural one for it. Anxiety is there as a matter of course colouring all its views and enterprise. The same holds for the genesis of many childish phobias. These are often the crystallization at one point of a general sense of insecurity easily engendered in a young child facing a big and difficult world. Similarly with obsessive and compulsive conditions the part played by the stage of development of thinking (sympathetic magic) in determining their almost universal incidence must be investigated in their relation to instinctive tendencies. Of hysterical conditions it may be said that again a common-sense evaluation is required. The problems of the hysterical constitution and of hysterical dissociation have not by any means been finally met by the hypotheses so far advocated.

All these problems about which there is at present so much speculation offer a promising field for really scientific investigation. The psychiatrist who so often sees only the end results envies the paediatrician his opportunities of seeing the beginnings of watching personalities in the making and of guiding them towards healthy happy achievement.

RESULTS OF TREATMENT IN EXOPHTHALMIC GOITRE

BY

FRANCIS R. FRASER, M.D., F.R.C.P.

PROFESSOR OF MEDICINE, UNIVERSITY OF LONDON; DIRECTOR MEDICAL PROFESSORIAL CLINIC, ST. BARTHOLOMEW'S HOSPITAL

THERE is considerable uncertainty in the minds of many medical men as to the place of surgery in the treatment of toxic goitre, by which is meant not only exophthalmic goitre but also those closely related conditions in which there are manifestations of thyroid intoxication such as the so-called 'toxic adenoma.' It may be of interest therefore to review the results of treatment in a series of patients, some of whom were treated by thyroidectomy and others by various methods but without thyroidectomy.

All the patients in this series were admitted to the wards under my charge during 1920–25, and since then have been recalled from time to time only those who have been seen this year or of whom reliable reports have been received this year will be considered. A period varying from five to ten years has now elapsed since their admission to hospital. They all remained under direct observation in the wards for several weeks at least and in some instances for several months during which time many lines of treatment and investigation were tried according to the ideas or clues we were working on at the time but neither x-ray treatment nor radium was employed, so that although the number is small they have been carefully observed. They were admitted because they were the more serious cases and they include such patients as those with heart failure in preparation for surgical treatment and similar cases in which surgical treatment was not carried out for one reason or another. The two groups—those treated by thyroidectomy and those treated by other methods—though not strictly comparable as regards the severity of the disease are similar to a considerable extent since many patients in whom thyroidectomy appeared advisable refused to undergo operation and because we are always ready to delay operation if possible so that other methods of treatment can be tried. As a rule thyroidectomy was advised in the more severe cases and in those that proved resistant to other method of treatment.

Of the 60 patients there is no report for 1930 in 10 and of the remaining 50, 24 with an average age of 38 years, were treated surgically and 26 with an average age of 35 years by means other than thyroidectomy. Of the 24 treated surgically the results (Table I) are good (capable of full work) in 15, poor (working with difficulty) in 5, bad (leading invalid life) in 1, while 3 are dead. Of the 26 treated by non-surgical method the result are good in 10, poor in 4, bad in 2, while 10 are dead. The principal difference in the results in the two groups is the much higher mortality in the non-surgical group. Even if two patients who died in hospital of conditions not apparently connected with the thyroid disease are omitted the difference in the mortality in the two groups is striking.

TABLE I

Treatment	Total Number	Average Age	Result			
			Good	Poor	Bad	Died.
Surgical	24	38 years	15	5	1	3
Non-surgical	26	35 years	10	4	2	10
	0		25	9	3	13

The patients can be subdivided into those with primary and those with secondary Graves's disease although the distinction cannot always be made with confidence. The essential disturbance that produces the thyroid intoxication is unknown but is probably the same in both. In primary Graves's disease, however there is no evidence of previous structural change in the thyroid gland the characteristic histological changes are found throughout the whole gland and the subjects are usually young adults. The signs of intoxication may be very severe this group includes the typical cases of exophthalmic goitre with the eye signs tachycardia tremor vasomotor and nervous disturbance. In secondary Graves's disease the disturbance arises in a patient who has a damaged thyroid gland already as shown by coarse or fine fibrosis colloid goitre local areas of degeneration etc. the histological changes characteristic of the disease are found distributed in a patchy manner, and the subjects are commonly more advanced in years. The signs of intoxication are usually mild eye signs and vasomotor disturbance may be absent but the functions of the other organs of the body may be seriously crippled possibly because they are older. The patients with but slight evidence of thyroid intoxication but with auricular fibrillation and heart failure belong as a rule to this secondary group.

The classification of patients that were treated by non-surgical method into the primary and secondary group reveals (Table II) that the good results are found mainly

TABLE II.—*Treated by Non-Surgical Methods*

Type	Total Number	Average Age	Results			
			Good	Poor	Bad	Died
Primary	16	8 years	8	3	1	4
Secondary	10	47 years	2	1	1	6
	26		10	4	2	10

in the primary group (average age 28 years) and the mortality is greater in the secondary group (average age 47 years). Of the four fatal cases of primary Graves disease two patients died in hospital of conditions other than the thyroid disease but the other two were young females 15 and 25 years of age who were not seriously ill when in hospital but who did not remain under observation and relapsed later and died at home. The six patients with secondary Graves's disease who died had an average age of 45 years one aged 39 had been ill off and on for twenty years and died horribly after admission with an acute severe intoxication one aged 53 died after discharge but no operation was advised because of the presence of pulmonary tuberculosis and the remaining four died after discharge in acute exacerbations of the thyroid disease having refused operative treatment while in hospital. Of the six patients in whom the result is recorded as poor or bad two have since undergone operation and are now improving and two others have refused operation. Of the ten patients in whom the result is recorded as good two, aged 65 and 36 years,

had secondary Graves's disease, were not seriously ill, and improved rapidly under treatment, the remaining eight were young females (average age 26 years) with primary Graves's disease who either improved rapidly with treatment, or were in such domestic and financial circumstances as to allow of prolonged rest under supervision In one of them the result could not be called "good" until as long as six years after commencing treatment, and as long as eleven years from the onset of the disease

Those that received surgical treatment (Table III) can be classified about equally in the primary and secondary groups, with average ages of 29 and 44 years respectively

TABLE III—*Treated by Thyroidectomy*

Type	Total Number	Average Age	Results			
			Good	Poor	Bad	Died
Primary	10	29 years	8	1	0	1
Secondary	14	44 years	7	4	1	2
	24		15	5	1	3

One only of the deaths occurred immediately after operation, the other two patients (aged 44 and 49 years) who died had one lobe only removed, and died later in acute relapses, three and six years following the operation Of the six patients in whom the results are recorded as "poor" or "bad," one has recently had a third operation, at which the thyroid gland was found to have grown to a considerable size from the remnant left at the previous operations, and is now doing well The remaining five may require further operative treatment also, but in them case there are factors that make a decision difficult

Conclusions

The number of patients is too small to be of statistical value, nor are the groups strictly comparable, but the results after periods varying from five to ten years after discharge from hospital confirm the impression gained from the experience with a much larger number that have not been under observation for so long, or have not been studied so carefully The nature of the results in the patients treated by surgery will depend, of course, on the experience and skill of the surgeons available The following conclusions, however, seem justifiable Of patients whose condition is severe enough to require admission to hospital, surgical treatment is indicated in the present state of knowledge in those with secondary Graves's disease It is indicated, also, in those with primary Graves's disease who do not improve rapidly, or who continue to relapse and become chronically ill in spite of satisfactory management, or who for financial or other reasons cannot submit to adequate observation and treatment In a number of the younger patients with primary Graves's disease recovery takes place without surgical treatment but observation and treatment extending over years may be necessary

THE AFTER-HISTORY OF HEALED SURGICAL TUBERCULOSIS

BY

L. D. TELFORD, F.R.C.S.,

PROFESSOR OF SYSTEMATIC SURGERY, UNIVERSITY OF MANCHESTER

The treatment of non-pulmonary tuberculosis has passed through various phases in the last thirty years In the earlier days treatment was mainly by operation, and tuberculosis was regarded as a local disease to be eradicated by painstaking removal Hence, free and often elaborate excisions of joints were widely practised In the end the unfortunate outcome as regards the local disease, no less than the frequency of disastrous functional results, caused the methods of radical excision and erasion to fall into deserved disuse

This was hastened when it was realized that tuberculosis of a joint is not the primary condition, but is a pyaemic manifestation in a patient already infected in another spot Obviously, if this view is correct—and there can be little doubt that it is—the most extensive local procedure will not cure the disease In conformity with this view, treatment then swung over to conservative methods aiming to raise the resistance of the body by general treatment and handling the local condition by rest in the optimum position for a prolonged period The results of this method are on the whole good, but they fall short of ideal, and in recent years the question of operative treatment has again been seriously raised by thoughtful surgeons

It is clear that in the present state of our knowledge our main curative agent in tuberculosis is rest The rest given by any form of external splint, however carefully applied, is at the best incomplete If by operation we can induce ankylosis of a tuberculous joint, either by intra-articular or extra-articular technique, that joint will almost certainly heal The object of the modern revival of operation is therefore not immediate eradication of disease but ultimate cure by production of an ankylosis

Any surgical method, however sound in theory, must in the end stand or fall by its results, and it is unfortunately very difficult to estimate with any accuracy the end-results in surgical tuberculosis This communication has been written in no spirit of controversy but simply with the object of contributing certain data which may be useful in any discussion of the respective merits of the conservative and operative methods The author has had the advantage of treating this type of case during twenty six years in one institution by conservative methods, involving, in addition to the usual resources of general treatment, a somewhat rigid fixation by plaster or *appliance In these* respects the series has the advantage *of being* very homogeneous, but the difficulties in arriving at an accurate idea of the results are great

The main stumbling-block is diagnosis How is one to be sure that a given case is really tuberculosis? In the series here discussed all that can be said is that every care has been taken, by clinical examination, by skiagram, and, where available, by examination of aspirated material, before a diagnosis of tuberculosis was accepted While the grosser errors—for example, syphilis, actinomycosis, haemophilia, the varying dystrophies of the type of pseudocoxalgia, and the more obvious infective joints—can be eliminated, who is to say what other conditions may still be hidden in the dump we call surgical tuberculosis?

In a previous communication[1] I endeavoured to estimate the more immediate results of conservative treatment, the object of the present inquiry is to estimate, as far as may be, the ultimate fortune of those patients who are discharged as cured

The investigation concerns a total of 170 cases of children who have been under my care for tuberculous disease of the larger joints These patients comprise 67 suffering from disease of the spine, 71 with disease of the hip-joint, and 32 where the lesion was in the knee-joint All these patients were discharged between the years 1906 and 1924 with the observation "apparently cured" None of the patients examined has been discharged from the institution for a shorter period than six years, and the length of time which has elapsed since their apparent cure ranges from six to no less than twenty-four years

Of the 170 patients, I have been able to find 129, and their present condition is exactly known The proportion of cases traced must be regarded as satisfactory when one considers the very floating nature of the population in a large industrial city

In classifying the results, the method adopted is as follows

Class A includes all patients found to be in good health with no sign of activity in the old disease and no fresh focus of tuberculosis They are all either at work or quite capable of doing active work These number 110

Class B comprises cases in which there is *complete* arrest of the disease, as in Class A but the functional result is not good, the patients, who number 7, must be regarded as cripples

Class C contains those cases which show the original disease in a still active form or have had some other sign of tuberculous infection Of these there are 6

Class D includes patients who have died since discharge There are 6 of these and with one possible exception in which death is stated to have been due to influenza they have all died of tuberculosis of lung or kidney

The main fact which emerges is that out of 129 patients who are known, no fewer than 110 remain perfectly well These figures are in welcome contrast to the gloomy views often expressed which are usually the vaguest of impressions not backed by any actual figures Pessimism in tuberculosis is due mainly to the fact that, as with other diseases it is chiefly the failures that come back

Finally it is contended—and probably with reason—that operative treatment may shorten the length of the time needed for recovery In this respect it is worth noting that the average residence in the institution of these 170 patients was three years and two months

RADIUM IN THE TREATMENT OF MENORRHAGIA AND IRREGULAR UTERINE HAEMORRHAGE.*

BY

MALCOLM DONALDSON, M.B., F.R.C.S.,

PHYSICIAN ACCOUCHEUR WITH CHARGE OF OUT PATIENTS ST BARTHOLOMEW'S HOSPITAL.

So much work has been done in the treatment of malignant disease by radiotherapy that it is easy to overlook the value of such treatment in non-malignant conditions such as haemorrhage and menorrhagia caused by fibroids or associated with the menopause

Twenty or thirty years ago students were taught that if a patient was diagnosed (after curettage) as having "menopausal haemorrhage" it was only necessary to use palliative remedies and to reassure the patient that all would be well in a year or so, when the "change of life" was over In actual practice this meant that the unfortunate woman was doomed to a C3 life for several years, and only if she became dangerously anaemic was hysterectomy resorted to Nowadays all that is entirely changed

DIAGNOSIS OF IRREGULAR HAEMORRHAGE

At the present time it would be superfluous to emphasize the importance of a careful physical examination if a patient complains of this symptom Irregular haemorrhage is so often the first symptom of malignant disease that every student is taught that to treat a patient suffering from irregular haemorrhage or menorrhagia without such an examination is malpraxis almost amounting to criminal negligence

It is unfortunate that the public is not equally aware of the importance of irregular haemorrhage and menorrhagia It is true that very often such symptoms are of a temporary nature and have no serious consequences and it is this fact that makes it so difficult to educate women to regard them as needing immediate attention In the past the medical profession has contributed to this attitude of mind by the wait and see principle of treatment which was very frequently adopted especially in cases of menopausal haemorrhage

What then are the rules which should be laid down for dealing with the patient who complains of menorrhagia or irregular bleeding? The first thing is to take a careful history which together with a general physical examination, will exclude such conditions as haemorrhage connected with pregnancy high blood pressure etc Next a physical examination of the genital organs especially the cervix uteri will exclude such conditions as carcinoma of the cervix, fibroids etc If there are no gross abnormalities it is then permissible to treat the patient symptomatically for a week or two If at the end of a month there is no improvement the uterus must be explored Only after such exploration is it justifiable to say that the condition is due to an endocrine disturbance such as is found at the time of the menopause

TREATMENT

Having now decided that the patient is suffering from an endocrine disturbance which is not benefited by drugs the question of treatment will depend first on the age of the patient If the patient is over 40 then there is no doubt that the right treatment is to create an artificial menopause by means of radiotherapy

Before discussing the particular technique it is as well to consider the pros and cons of such a procedure The advantage of getting rid of this troublesome symptom of haemorrhage once and for all is obvious and borne out by the numerous letters of gratitude that one receives What then are the disadvantages?

The objection of course is the onset of menopausal symptoms—namely, flushing sweating headaches etc The question has been asked whether these symptoms are any more pronounced in a menopause which is artificially produced than those which occur when nature brings about the menopause in the course of time It is a point which it is almost impossible to solve by means of statistics but my impression is that, after the age of 40, there is really very little difference

If, however the question arises of producing an artificial menopause in a patient under the age of 40, the problem is very different First there is an obvious objection to cutting short the youthful characteristics of such a patient at an early age Secondly there is some evidence that the symptoms caused are distinctly more severe than those found in patients over 40 It is true that in some of the young patients in whom those symptoms have been noticed the treatment has consisted of a small dose of irradiation, purposely administered in the hope of causing a temporary amenorrhoea and it is possible that the increased symptoms are due to a partial destruction of the ovarian activity The same sequelae have been observed in a patient who has had an operation leaving only a small portion of one ovary

When once the decision has been made that it is advisable to create an artificial menopause the question arises as to what method should be employed There are two radiological methods by which the artificial menopause may be brought about (*a*) radium (*b*) x rays

If a patient is suffering from irregular haemorrhage it is impossible without exploring the uterus to exclude a cause such as malignant disease or a polypus For this examination an anaesthetic is necessary and under these circumstances the correct procedure is to place 50 mg. of radium in the uterus. If on the other hand the patient is suffering purely from menorrhagia then it is fairly certain that the condition is not due to malignant disease In these circumstances it is justifiable to use x rays without any exploration of the uterus the advantage of this method being the fact that no anaesthetic is required and the patient is not obliged to lie up in bed

Technique of Radium Treatment

The technique for using radium in the case of a patient who is over 40 is very simple The patient is given an anaesthetic and after a careful bimanual examination the uterus is dilated and carefully curetted If nothing abnormal is discovered then a tube containing 50 mg. of radium element the length of which is no more than 2 inches is placed inside the cavity of the uterus The walls of this tube must be the equivalent of at least 0·5 mm of platinum and in addition it is better to screen the metal filter with 2 mm of rubber so as to cut off secondary rays The length of time which the tube should be left in is still a matter of controversy The majority of gynaecologists consider twenty four hours sufficient but in a large uterus with the ovaries near the pelvic wall, this sometimes fails to produce a permanent

* Read in opening a discussion in the Section of Radiology at the Annual Meeting of the British Medical Association in Winnipeg 1929

amenorrhoea At St Bartholomew's Hospital we did a series using seventy-two hours, the results of which will be discussed later We are now doing a series leaving the radium in for forty-eight hours, and this, in my opinion, is the optimum duration for the application

Technique of X-Ray Treatment

My colleague Dr Finzi has sent me the following description of his methods

'As used in England, *x* rays are generally employed in doses that will cause complete sterilization in patients over 38 or 40 Smaller doses have been used with the idea of reducing the menorrhagia, but their use is very tricky, and they take a long time to act The larger doses will produce a temporary sterilization in younger patients, but there is then a danger that, if conception takes place when the ovaries are just beginning to recover, the offspring may be malformed, microcephaly being the most usual abnormality

The action of *x* rays is not entirely an action on the ovaries but in the case of fibroids there is a direct action on these also

The method which I have used for many years and have found so satisfactory that I have not thought advisable to drop it as a routine, is a split dose, repeated method

"A filter of 5 mm of aluminium is used, 140 to 150 kilovolts (interrupted current), and a moderately full erythema dose is given to the skin Two anterior ports of entry are used, and the applicator, applied with compression, is sloped, so that both ovaries get some of the rays One or two posterior fields are employed, according to the stoutness of the patient, generally one One of these fields is given on each of three or four successive days This series of fields must be repeated on two further occasions, and it is most important that the beginning of the second series should be four weeks after the first and the beginning of the third series four weeks after the second The dose is slightly reduced for these subsequent treatments to compensate for the decreased tolerance of the skin

'This method results in very little discomfort to most patients and they can usually continue their ordinary avocations even during the treatment

"The other method, which I employ for patients who live far away is to sterilize in one treatment This is a far more severe procedure for most patients A filter of 0 5 mm of copper or zinc is used, 180 kilovolts continuous current, and two three, or four fields at a 30 cm distance Less than an erythema dose is needed

'Whichever method is used, the result is very certain in competent hands I have not failed out of more than sixty cases which I have treated myself

Compared to radium its action is slower, as there is no direct action on the mucous membrane of the uterus as with radium One period, often very prolonged, is the rule after the first *x* ray treatment and, during this, the menorrhagia is not diminished A second period may occur, but is usually much less severe A third period is very rare This applies whether the single dose or the split dose technique is used

One advantage over radium is that *x* rays can be satisfactorily used with quite large fibroids (My second case had a mass reaching the ensiform cartilage and it gradually disappeared)

X rays I find, is usually—not always—less trying to patients than radium in the uterus The fact however, that *x* rays can be used without an anaesthetic is rather a snag, as the examination under an anaesthetic may be necessary to determine whether there are any contraindications to the treatment"

ACTION OF RADIUM IN PRODUCING MENOPAUSE

It was at one time thought that radium brought about amenorrhoea in a different way to *x* rays It was suggested that the radium acted purely on the endometrium, while *x* rays acted entirely on the ovary This theory was upheld by Forsdike in his Jacksonian Essay, "The effects of radium upon living tissues" His evidence, however, that it is not due to destruction of the ovary, is a little confusing He states that only two out of ten young women between the ages of 29 and 38 suffered from flushes This certainly is a small proportion but if even two suffered in this way, is it not evidence that the ovaries were affected?

Turning to his histological evidence, he bases this on sections of an ovary removed after irradiation The experimental evidence, where radium was placed 8 cm from the ovary, is certainly more convincing

In my experience there is considerable evidence against the theory that radium acts only on the endometrium For instance, in quite a large number of cases there have been two periods following the radium application It might be argued that in these cases sufficient changes had not taken place in the endometrium to prevent the flow of blood, but if this is so, why did the same dose produce in some of the young women only a temporary amenorrhoea? It would be very difficult to explain these observed facts by an action on the endometrium, but it is not so difficult to explain them if we believe that radium acts on the ovaries It is well known that menstruation is related to ovulation, and the Graafian follicle which is ruptured or is mature enough to be on the point of rupturing is not so readily affected by radium as the young rapidly growing follicle In the elderly patient it is probable that the follicles that are likely to be associated with menstruation within the next few years are destroyed by the radium, but not those one or two follicles which are already mature, and this would explain the fact that patients sometimes menstruate once, or even twice, after irradiation

Again, in the case of a young patient, the cells which will eventually become a follicle are not undergoing sufficient active metabolism to be affected by the rays, and therefore, a year later, will become mature follicles, and will then rupture to form a corpus luteum, which on degeneration will be associated with menstruation

DISCUSSION OF RESULTS

The results of creating an artificial menopause are fairly well known statistics obtained at University College have recently been published by Asherson[1]

In this series, 63 cases were treated for menopausal menorrhagia Of these 63, 55 were cured by one application of radium Six required two applications, 4 were untraced, and 1 had a small dose without results These patients were all over 40 years of age Six of them required a second dose, compared with two in the Bartholomew's series, which suggests that the rather larger dose used in the latter institution is more certain in its results

In the same series, 23 cases were treated for "essential menorrhagia" These are of particular interest All of them were under the age of 40, and of these, 16 cases had a restoration of normal menstruation Five cases had permanent amenorrhoea The dose given to these patients varied from 50 mg used for eight hours up to 50 mg for fifty hours

It is clearly shown from these results (1) that the younger patients will stand a much bigger dose without producing amenorrhoea, (2) that this method of treatment must seriously be considered in certain cases even if the patient is under 40 before resorting to hysterectomy

The disadvantage is the fact that, owing to the position of the ovary being unknown, it is impossible to be certain of getting a dose that will be efficient and yet not produce permanent amenorrhoea

The other series recorded by M L Kreitmayer, in his paper on page 815, consisted of 122 cases treated at St Bartholomew's Hospital Of these patients, 97 were traced, and answered a questionary As the author states, a questionary is not the ideal method of getting evidence but the answers were sufficiently definite to justify publication It is hoped that these patients will be persuaded to return to the hospital so that more details can be obtained

It would appear from these figures that of 97 cases, 90 patients were cured with one dose, while 7 required further treatment Of these 7, 5 were under the age of 40, thus bearing out the idea that it is more difficult to produce an artificial menopause in a young patient

With regard to menopausal symptoms, the answers were not very definite, it would appear, however, that 15 patients had no flushes at all Of those who had flushes, some have continued for as long as five years

There is some controversy as to whether these menopausal symptoms are more severe after a menopause artificially produced than one occurring as a result of age This, of course, is a very difficult problem to solve by statistics It is my impression that there is little differ

[1] *Journ Obstet and Gynaecol*, 1929 xxxvi, No. 4, 778

ence in patients who are treated over the age of 40, but that in the younger patients the symptoms tend to be more severe

A question often asked by patients before submitting to this treatment is 'Shall I get fat?' It would appear from this series that 50 per cent definitely put on weight, but details of how much are not recorded

Another important symptom is the question of dyspareunia which occurred in only 7 cases out of the 93 and loss of inclination was experienced in 8 In 31 cases it is definitely stated that the relations were unaltered Forty of the remaining patients however, were spinsters or widows, and in 5 the answers were too indefinite to be of value The small number of cases suffering from dyspareunia suggests that there is no real trouble caused by cicatrization or adhesions in the vagina in spite of the large dose—that is, 3 600 mg hours

Treatment of Fibroids by Radiotherapy

The treatment of fibroids may be divided under three headings—surgical radiological and palliative

A few years ago the palliative treatment was frequently employed, especially when the patient was over 40 and approaching the menopause, with the idea that once the menopause was complete the symptoms of menorrhagia would cease and the fibroids diminish in size Unfortunately this process often lasted over a period of several years

Such treatment is now confined purely to cases where the patient is young the symptoms very slight the fibroids small, and where it is undesirable that the patient should have any drastic treatment until all hope of pregnancy is abandoned when some more radical measure such as myomectomy, is undertaken which will not only relieve the symptoms but may bring about fertility

The indications for radiological treatment are at present somewhat limited The majority of gynaecologists consider that, if the patient is over 40 and the symptoms are menorrhagia or irregular haemorrhage and the fibroid is not sufficiently large to cause pressure symptoms—that is to say, not larger than a fist—and if there is no inflammatory condition in the pelvis then such a case should undoubtedly be treated by radiotherapy

The question then arises whether radium or *x* rays should be employed Here again the rule is very much the same as in the case of creating artificial menopause If the fibroids are associated with irregular bleeding it is essential that the uterus should be explored Fibroids are very frequently associated with sterility and it is in the nulliparous patients that carcinoma of the body is most likely to occur If therefore the uterus is to be explored in order to exclude malignant disease then a 50 mg tube of radium element should be inserted into the body of the uterus to bring about an artificial menopause and thus to stop the symptoms of haemorrhage due to the fibroid

On the other hand when the fibroid produces pure menorrhagia it is quite justifiable in such a case to use *x* rays, as mentioned in the preceding section

Conclusions

1 In cases where the patient is over 40 years of age and suffering from irregular haemorrhage without a gross pathological lesion the production of an artificial menopause by means of radium is the treatment of choice if drugs fail

2 The optimum dose of radium seems to be 50 mg of the element screened with not less than 0·5 mm of platinum and kept in the uterine cavity for *forty-eight* hours

3 In cases where the patient is over 40 years of age and suffering from pure menorrhagia without any gross pathological lesion *x* rays should be considered as an alternative method of producing an artificial menopause

4 In young women where other treatment has failed to cure the symptom of uterine haemorrhage or menorrhagia, radium has been used successfully to cure this symptom but there is a risk of permanent amenorrhoea and severe menopausal symptoms which perhaps makes subtotal hysterectomy preferable in the majority of cases

AFTER-EFFECTS OF INTRAUTERINE RADIUM FOR THE PRODUCTION OF ARTIFICIAL MENOPAUSE

Report of an Investigation

BY

M I KREITMAYER MRCS LRCP

(From the Gynaecological Department of St Bartholomew's Hospital)

The present investigation was undertaken at the suggestion of Dr Malcolm Donaldson in order to obtain definite figures for the degree of success of the primary objective—that is the production of amenorrhoea—and also to gain some idea of the nature of the sequels such as menopausal symptoms The cases in the series were all treated in the gynaecological department of St Bartholomew's Hospital during the years 1925 to 1929 inclusive under the care of Dr J Barris, Dr M Donaldson, and Dr W Shaw to all of whom I offer thanks for permitting me to have access to the notes Essentially the type of case treated was that in which there was excessive or irregular uterine haemorrhage with no gross abnormality detectable on visual and bimanual examination under anaesthesia The majority of women treated were near the menopause A small proportion were women of under 40 years of age suffering from menorrhagia and one patient was treated for dysmenorrhoea In no case was there found any evidence of malignant disease

Technique

With the patient anaesthetized and in the lithotomy position the vagina and cervix were first inspected, and then a careful bimanual examination was made The cervix was then dilated and curettage for section performed The radium in its container was then inserted, and kept in position by gauze packed into the vagina

The dosage usually given was 50 mg element screened by a minimum of 0·5 mm thickness of platinum and kept in position for seventy two hours in other words a dosage of 3 600 mg hours Of the 97 patients forming the present series 53 received this amount but 1 patient received as little as 480 mg hours and 3 as much as 7 200 The dosage in the remainder fell between these limits The ages of the patients ranged from 20 upwards 3 were in the twenties 14 in the thirties 57 in the forties 22 in the fifties, and 1 was in the sixties

The actual number of patients treated was 122 but of these only 97 were traced each of these received a questionary accompanied by a letter suggesting that he should consult her doctor if she had any difficulty in making out the answers It was hoped in this way to minimize inaccuracies The questionary was as follows

A Have you had any bleeding or monthly period since your radium treatment
  If so When did it start?
  When did it finish?
  How often did it occur?
  Give dates if possible
B How do you feel in yourself?
  Do you feel better or worse since your radium treatment?
  Do you feel the same as before your radium treatment
C Have you had any hot flushes since your treatment?
  If so how often did they occur?
  How long ago did they end?
D Have you had any sweatings?
  How long do the sweats last?
E. Have you suffered from depression since the treatment?
  If so for how long?
F Are you more cheerful?
  Are you more irritable
  Are you more depressed?
G Have you put on weight or lost it since your treatment?
H Have you had any pain since your treatment
  If so where was the pain
I Have your relations with your husband altered since the treatment?
  If so how?
K. Have you had other trouble since the treatment such as discharge (such as whites) pregnancy instead of facial neuralgia

The following is an analysis of the replies

Question A

All the patients answered this question 47 reporting no bleeding at all following the treatment and 50 some

bleeding of varying severity The 7 of whom particulars follow required further treatment

A B, aged 35, was treated in August, 1926, with 10 mg element applied for forty eight hours she had severe recurrence, and hysterectomy was carried out in another hospital

C D aged 29, was treated in January, 1929, with 50 mg for seventy two hours she had a severe recurrence, and hysterectomy was carried out in July 1929

E F, aged 37 was treated in January, 1929, with 49 mg for ninety six hours she had severe recurrence, and hysterectomy was carried out in October, 1929

G H, aged 33 was treated in June, 1926, with 50 mg element for ninety-six hours, and in May, 1927, she was treated for recurrence by means of x rays Since then she has had amenorrhoea, except for some bleeding in August and September, 1929

I K, aged 44, was treated in May, 1927, with 50 mg element for seventy two hours, a recurrence was treated in September, 1927, with the same dose, and since then the patient has had amenorrhoea

L M, aged 38 was treated in April, 1928, with 50 mg for seventy two hours In January, 1929, a recurrence was treated with the same dose and since then the patient has had amenorrhoea

N O, aged 40, was treated in December, 1927, with 50 mg element for fifty two hours A recurrence was treated in May, 1928, with 50 mg element for forty-eight hours, since then she has had occasional bleeding, but diminishing in amount

The after-history of the remaining 43 is as follows 5 had slight bleeding immediately following the treatment, 25 within the first two months, and 3 within three to six months, 7 had occasional bleeding from six to eighteen months after treatment In these 40 cases bleeding has now stopped In 2 cases treated in 1928 with 50 mg element for seventy-two hours bleeding still occurs at irregular intervals, but no further treatment has been carried out The remaining case was treated in December, 1925, for dysmenorrhoea with 50 mg element for seventy two hours There was some bleeding from January to March, 1926, and then amenorrhoea till January, 1929 Since then periods have occurred, not excessive in amount, at the normal rhythm of twenty-four days dysmenorrhoea has disappeared

Question 3

This question was answered by 93 patients, of these 76 say they feel better, 3 that they feel worse, and 10 that their condition is unchanged No definite conclusion could be derived from 4

Question C

This question was answered by 93 patients, but on the whole the answers were vague It seems clear that of 77 who have had flushes 62 still have them, and of the remaining 15 6 state that the flushes have ceased, and 9 have failed to answer this part of the question In the 6 cases from which this symptom has disappeared the flushes persisted after treatment for a period ranging from six months to three years

Question D

The purport of this question does not seem to have been quite clear to the patients, but 52 state that they have had sweats, and 39 that they have had none, the remainder give indefinite answers The average duration of sweats appears to have been five to ten minutes, but there are no data about their frequency

Question E

Of those who give definite answers to this question, 59 state that they have suffered from depression, and 32 that they have not Only 21 attempted to answer the second part of the question, and of these 8 state that the depression lasted for periods varying between one and twelve months after treatment, 2 that it lasted for two years, 4 that it lasted for three years, 5 that depression is experienced occasionally, and 2 that it is experienced frequently

Question F

Definite answers were received from 75 patients, 43 of whom claim to have been more cheerful, 22 more irritable, more depressed, or both, and 10 unchanged in spirits since the operation

Question G

Answers were received from 79 patients, of whom 46 have gained weight, 18 have lost weight, and 15 said that their weight is unchanged

Question H

To this question there were 91 definite replies, 52 patients said that they have had pain since the operation, 39 that they have not, of the former, 27 state that the pain has been in the lower abdomen, lower part of the back, or groins, 19 that it has been in the head, arms, chest, etc, and 6 are vague on the subject

Question I

To this question the replies of 40 of the patients were irrelevant, as they were spinsters, widows, or others who for some reason had had no sexual relations since treatment Of the remainder, 31 stated that their relations were unaltered, 8 that they had lost inclination, 7 that they suffered from dyspareunia, and 2 that they bled after coitus, 5 were indefinite

Question K

To this question the answers are necessarily varied, 41 complain of discharge, though many of these state that the discharge only lasted for a short time after treatment, 41 complain of indigestion, 54 of headache, and 54 of nerves None have become pregnant

ANALYSIS OF RESULTS

It will be seen that from the point of view of the production of amenorrhoea the treatment has been satisfactory, but it is worth while analysing the nine cases in which the initial dose of radium failed to bring about a cure In this group six of the patients were under 40, one was 40, and two were between 40 and 50 Only one of the six under 40 had received a small dose—namely, 480 mg hours, the remainder receiving 3,600 mg hours or over The patient aged 40 received 2,600 mg hours, and the other two 3,600 each Estimating failures as a percentage of patients within the same age group it will be seen that 35 3 per cent of failures occurred in the cases under 40, and 3 75 per cent in the cases over 40 The series is too small to generalize from, but the figures accord with the view that the younger the patient is the more resistant are her organs likely to be to the effects of radium

The fact that 77 of the patients complain of flushes, 52 of sweats, 59 of depression, 54 of headaches, and 54 of nerves, suggests that menopausal symptoms are prominent sequels of the treatment In spite of these menopausal symptoms, however, 76 of the patients said that they are better, 10 that they feel just the same, and only 3 that they are worse Although a large proportion complain of pain, one cannot say how much of this is due to the treatment, or even if the pain was present or not before the treatment

PNEUMONOCONIOSIS DUE TO FLUE DUST.

BY

W E COOKE, M D, F R C P Ed, D P H

THE special interest of the following details turns on the fact that we have been unable to trace a similar case in medical literature

A post-mortem examination was performed on a man, aged 35 at the time of his death Between the ages of 14 and 25 he had been employed as a riveter in a boiler works For the subsequent nine and a half years he had been a boiler cleaner, an occupation which included flue cleaning

There was no family history of tuberculosis, and except for an attack of pneumonia in 1917, and again in 1918 (probably influenzal), and an attack of influenza in December, 1929, his previous health had been good In May, 1930, his teeth were extracted for pyorrhoea On July 1st he complained of hoarseness and lassitude, and ceased work At the beginning of August he was placed under the care of the district tuberculosis officer Up to August 11th his sputum had been examined for tubercle bacilli on six occasions with negative results, but it was found positive on five subsequent occasions

An x-ray examination on August 13th revealed scattered mottling throughout both lungs, especially dense on the left, and the view expressed by the tuberculosis officer was

that the appearance was suggestive of advanced silicosis The patient died on September 5th, and a necropsy was performed on the next day

Macroscopical Appearances

There were dense pleural adhesions on both sides of the chest The right lung was almost coal black in colour small hard nodules were found along its anterior border and throughout its substance Several small cavities were present at the apex they were smooth walled and surrounded by dense fibrous tissue The lung generally was fibrosed and small scattered areas of broncho pneumonia were visible The left lung was voluminous heavy and dark grey in colour Small hard nodules were present throughout its substance which was markedly fibrosed At the apex were several small cavities with thick wall The rest of the lung was the seat of extensive broncho pneumonia

The bronchial glands were enlarged black in colour but not very hard The heart muscle was pale and soft and the mitral valve was clerosed and incompetent The liver was in the condition of chronic passive congestion with fatty change

Microscopical Appearances

Both lungs showed the condition of well marked pneumonoconiosis with extensive areas of fibrosis and obliteration of the smaller bronchi and vessels There was an excessive amount of dust in the fibrotic areas and dust cells were present in large numbers throughout the sections The alveolar walls were fibrosed and thickened and contained dust deposits and dust cells Caseation was occurring in some of the fibrotic areas certain of which showed giant cells and an atypical picture of tuberculosis In the right lung small areas of bronchopneumonia were present The histological appearance of the left lung differed only in degree from that of the right The fibrosis was more marked and the broncho-pneumonia which was undoubtedly of tuberculous origin was very much more extensive The bronchial glands showed some fibrosis and fine dust particles were scattered throughout the sections

Portions of the lungs were digested with trypsin and the mineral matter was examined microscopically In addition to an excessive quantity of fine granular dust much of which was carbonaceous large dark angular particles were seen and also flat mica like and small transparent crystalline particles of silica or silicates which ranged in size from the order of the ultra microscopic to 60 or more microns in length Some of the mica and crystalline particles were coloured red from the presence of iron Under the polarizing microscope the mica and silica particles were seen to be doubly refracting Similar particles were present in the flue dust in which he patient had worked Sections of both lungs and of the bronchial glands showed under the polarizing microscope a large number of doubly refracting particles presumably silica or silicates

From the history and the examination of the lungs there can be little doubt but that the pneumonoconiosis preceded the tuberculous infection by many years

Chemical Considerations

Chemical analysis of the lungs boiler scale and flue dust were made by Mr T H Byrom F I C The following tables indicate the components in 100 grams of the dried material

	Left Lung		Right Lung	
	Grams	Percentage of Ash	Grams	Percentage of Ash
Insoluble siliceous matter	0·142	3·03	0·178	3·56
Soluble siliceous matter	0·181	3·86	0·156	3·12
Total siliceous matter	0·323	6·89	0·334	6·68
Ferric oxide — —	0·120	2·56	0·450	9·00
Alumina — —	0·430	9·18	0·430	8·60

*Magnesium oxide †Ferrous oxide

The insoluble siliceous matter in the flue dust contains in addition to quartz grains many acicular crystals and flat plates, both transparent and opaque probably of micaceous and felspathic origin derived from the shale and other inorganic material from which the flue dust has been formed The occupation of boiler cleaner when Lancashire boilers are used includes flue cleaning The latter is by far the more dusty part of the work and was undoubtedly the primary cause of the pneumonoconiosis

It is of interest to note that three boiler cleaners are employed at the particular colliery at which the deceased worked During the past twelve years twenty seven men have been employed and have given up the work of these two are known to have died—on the subject of this communication, and another the cause of whose death is unknown One worked only one day and another one week Excluding these four the average duration of employment was fifteen months Including the two dead, the average period of work was twenty months The deceased man had worked the longest period 113 months the nearest approaching that time being thirty six months There is however a man still employed who has been at the work for sixty two months

TECHNIQUE IN ENDOTRACHEAL ANAESTHESIA[1]

BY

I W MACILL M B, B Ch,

ANAESTHETIST TO THE WESTMINSTER HOSPITAL

Not many years ago the administration of an endotracheal anaesthetic was outside the routine of the operating theatre Its introduction excited such interest as would be accorded to the performance of an unusual or difficult operation It is not improbable perhaps that the procedure was at first regarded as an unnecessary complication Doubtless also the patience of many a surgeon has been sorely tried on a busy operating day by the first attempts of his anaesthetist

Within recent years the advantages of the method have become widely known Surgeons are increasingly anxious to avail themselves of these advantages and many expert anaesthetists in England now employ the method as a routine for operations which formerly involved many anaesthetic difficulties

Nevertheless in some hospitals endotracheal anaesthesia is not available when required in cases where the result can compare unfavourably with those obtained by older and more orthodox methods Since the method can no longer be considered new—and if we grant that it has advantages—it is apparent that there must be some drawbacks to its unqualified employment

[1] A paper read in opening a discussion in the Section of Anaesthetics at the Annual Meeting of the British Medical Association at Winnipeg

Importance of Intubation Technique

In modern scientific work some of the most valuable advances have been the outcome of a study of technique It is my intention to apply this principle to the present subject, and to point out that most of the advantages of endotracheal anaesthesia are available if the anaesthetist will trouble to master the technique of intubation, if he does, the disadvantages become insignificant

Advantages and Disadvantages

The veriest novice knows that many of the difficulties in anaesthesia arise from a defective airway Whatever the cause, the syndrome is familiar—cyanosis, rigidity, laboured respiration—a vicious circle that is a heavy tax on patient, surgeon, and anaesthetist The ease with which an anaesthetic can be administered through a tracheotomy tube is an obvious contrast

It may be argued that in many cases such difficulties do not arise, and that in others the error can be rectified by the insertion of a pharyngeal tube of some sort But such a device cannot prevent obstruction at the larynx, and the anaesthetist must be constantly on his guard against such an occurrence In operations which do not actually increase the possibility of respiratory obstruction by their nature or situation, most of us are prepared to take the risk

A free airway can be established as a rule without interfering with the progress of the operation In those cases, however, in which endotracheal anaesthesia has proved itself most useful, there is no excuse for the anaesthetist who does not establish absolute control of the larynx before the surgeon operates This control can be secured at once by intubation, with the following results (1) The airway is free under all conditions (2) The patient can be protected against the entry of blood into the trachea (3) Control of the larynx makes it possible to maintain a light and even anaesthesia (4) The surgeon can be protected from the anaesthetic laden exhalations of the patient It is apparent that the provision by intubation of an airway that is practically proof against obstruction is the fundamental principle of the method

I wish to stress this point Many of us associate endotracheal anaesthesia with the true insufflation principle as described by Meltzer Auer, and Elsberg I hold that with the exception of those operations in which positive pulmonary ventilation is essential to life, low pressure, or no pressure gives adequate results Therefore elaborate apparatus is not absolutely necessary in every case The chief disadvantages are (1) the risk of possible trauma by the anaesthetist, and (2) the delay involved by intubation The importance of dexterity in intubation is now obvious and I propose to give you the results of my own experience

Position of the Patient's Head

Some of the chief difficulties which arise during intubation for anaesthetic purposes may be traced to a faulty position of the patient's head Hyperextension as adopted by some surgeons for bronchoscopy is not only unnecessary in most cases, but actually increases the difficulty of the procedure The position of the head in relation to the neck and trunk should be the same in the recumbent as in the erect position, this may involve the insertion of a pillow below the occiput When the position on the table is correct, the cervical vertebrae are in normal relation to the dorsal vertebrae and are not extended The head itself is slightly extended on the atlas, thus bringing the mandible into a position approximately at right angles to the table These, in fact, are the relative positions of the air passages instinctively adopted by a man standing in the normal erect position when he scents the air The natural air passage from nose to glottis is at its freest when such a position is adopted, the nose being the natural human respiratory passage

Let us consider a mesial section through the head and neck in this position It is clear that the course of the air passage from nostril to glottis is a curve A rubber tube with a similar curve, or a catheter mounted on a curved stylet, can be made to follow that course quite naturally, and will enter the glottis in a large percentage of cases, in fact, it will enter the glottis more readily than the oesophagus If a similar curved tube is passed through the mouth while the head is in the position I have described, it will almost invariably enter the oesophagus

Intubation can be carried out through the mouth or through the nose, according to the site of the operation In either case the position of the head is the same

Intubation through the Mouth

When the oral route is selected I prefer to pass the tube by direct vision with the aid of a speculum This instrument should have a wide slot at the side A self-contained battery in the handle is a convenient means of illumination

With deep anaesthesia associated with complete muscular relaxation and absence of reflexes in the throat, intubation through the mouth is easily performed But deep anaesthesia, such as is obtainable with ether, should be avoided if possible The aim of most of us is to exclude ether, or at any rate to limit its use to a minimum

When intubating through the mouth under light anaesthesia certain precautions facilitate the procedure and also prevent trauma

1 Preliminary cocainization of the pharynx and vocal cords with a fine nebulizer is of first importance This can be carried out before induction, or while induction is in progress The tendency towards reflex contraction of the pharyngeal muscles on passing the speculum is thus greatly diminished, and the glottis usually remains open I do not propose to discuss the obvious objections to this practice I have employed it for over ten years without any cause for regret

2 The teeth require particular protection under light anaesthesia It is best to insert a mouth prop before induction, and to protect the point where the speculum rests with a piece of sheet lead

3 On passing the instrument into the mouth the tongue should be manipulated to the left side, away from the slot, otherwise the organ may roll into the barrel and completely obstruct the view When the glottis appears, intubation should not be attempted unless the cords are apart Forcing a passage through the closed glottis is not only difficult, but likely to give rise to post-anaesthetic sore throat

Difficulty in obtaining a view of the glottis with the speculum can frequently be overcome by moving the proximal end of the instrument towards the right corner of the mouth This manœuvre permits the necessary extra elevation of the tip, and is preferable to hyperextension of the cervical vertebrae by lowering the head of the patient In my experience, the latter alteration in position is more likely to increase the difficulty than to alleviate it

Intubation through the Nose

I have described elsewhere[1] a method of passing rubber tubes and catheters into the trachea by picking up the ends in the pharynx with the aid of a forceps and direct vision laryngoscope

I have referred also to what I have called "blind intubation,"[2] which is performed without opening the patient's mouth "Blind intubation" through the nose is, in my opinion, the most valuable manœuvre in the whole technique, and, as nasal intubation is so frequently of value in intra-oral operations, I propose to consider it fully It has two advantages (*a*) that it can be carried out under light anaesthesia without muscular relaxation (one might even go further and say that light anaesthesia is advantageous as tonus of the jaw muscles actually draws the epiglottis away from the posterior pharyngeal wall), (*b*) that there is no risk of damage to teeth or growths by the speculum

If you recollect my observations on the correct position of the patient's head, the facility with which intubation can be performed in this way is apparent It is so easy

in most cases that when a free choice is presented, and when there is no contraindication I always select the nasal route This experience has also been borne out while teaching students

Technique of "Blind Intubation"

It is clearly essential that free nasal breathing should be present on at least one side, and where a difference in degree exists the side which is most patent should be selected This point should be determined before induction Cylindrical gum elastic catheters up to size 23 (French gauge) can usually be passed through the adult nose without causing injury It is inadvisable, in my opinion to use a larger tube of this or any other hard material if trauma and bleeding are to be avoided Catheters require a wire stylet bent in the form of a semicircle

Commercial rubber tubing is the most satisfactory material It is cheap and easy to obtain It is firm enough to maintain its patency and sufficiently resilient to pass over mucous membranes without causing injury Moreover in the process of manufacture and subsequent storage in coils rubber tubing becomes naturally curved This curve is essential if the tube is to follow the course of the airway from nose to larynx It also obviates the necessity for a wire stylet

The tube should be cut obliquely sterilized and lubricated with soft paraffin It is then passed along the floor of the nose close to the septum The course of the tube should be mentally visualized as is that of the needle in regional anaesthesia When a point is reached at which the respiratory sounds are heard at maximum intensity the tube will usually enter the glottis if pushed onwards during inspiration In the case of failure, before resorting to the speculum and forceps, rotation of the tube to one side or the other will frequently bring its end into the desired position Occasionally gentle manipulation of the larynx with the left hand may be required in addition In certain cases where the epiglottis is the obstacle the difficulty can be overcome by withdrawing the tube one inch and rotating it so that the concavity is posterior If pushed onwards in this position the end of the tube will frequently pass behind the epiglottis On again rotating to the original position with the concavity anterior the free end will enter the larynx

The commonest question I have had to answer in demonstrating this manœuvre is "How do you know the tube is in the trachea?" It seems to me obvious that if a tube 26 cm in length is passed through the nose in its entirety the presence or absence of the free ingress and egress of air through the lumen is sufficient evidence of its position Should the tube be in the œsophagus or coiled up in the pharynx, no breath sounds are audible at the outer end

MAINTENANCE OF ANAESTHESIA

Having laid down the principle that intubation is of fundamental importance in endotracheal anaesthesia I shall now consider maintenance Here there is a choice of methods

1 In the classical method of Elsberg a catheter is used for intubation, and air or a mixture of anaesthetic gases delivered under sufficient pressure to prevent collapse of the lung (even though both pleural cavities are opened) and to prevent also the entry of pus or blood into the trachea at any phase of respiration Expiration takes place around the catheter and if the pressure is effective the clinical picture is not always a pleasant one The constant bubbling and spraying of blood by the return current obscures the operative field and as the pressure cannot be reduced with safety if there is any possibility of blood reaching the trachea the obstruction to expiration becomes a strain on the patient The surgeon also gets the full blast of the anaesthetic

2 This method[3] comprises the use of a catheter and in addition an expiratory tube which obviates most of the difficulties associated with insufflation through a single catheter It should be remembered that the return current no longer drives blood away from the larynx An effective pharyngeal gauze pack is therefore essential

3 In this method intubation is carried out with a tube the calibre of which is sufficient to allow free to-and-fro respiration The tube may be made of metal, of gum elastic, or of commercial rubber[2]

Anaesthesia can be maintained on ordinary inhalation principles, and the system may be open or closed

Several appliances and variations of technique have been devised in connexion with this method Flagg's metal cannula commends itself on account of its simplicity The Guedel and Waters inflatable bag provides absolute security against the entry of blood into the trachea besides other advantages Unfortunately however, neither of these appliances can be used through the nose and I trust that I have clearly pointed out the advantages of the nasal route for intubation

MATERIAL RECOMMENDED FOR INTUBATION

The material I have found to be most generally useful for intubation is commercial rubber, for reasons already stated About six sizes are necessary, varying from 3/16 to 3/8 of an inch in calibre The largest tube which the larynx will comfortably accommodate should be used An exception is made in the case of infants under one year for whom it is difficult to obtain a rubber tube with a wall which is thin enough and firm enough to maintain its patency under varying conditions of external pressure For these children I use a special thin-walled gum elastic catheter, size 7 (English gauge), and have found this satisfactory

APPARATUS FOR MAINTENANCE OF ANAESTHESIA

As already stated, when intubation is carried out anaesthesia can be maintained if necessary, without any apparatus other than a drop bottle and a piece of gauze over the outer end of the tube My own preference is nitrous oxide and oxygen with a minimum amount of ether This mixture seems to me to compare favourably with ethylene I use any efficient apparatus that is available in hospital work, but as bulk and portability are considerable factors in the conditions under which anaesthetists work in England I find a small continuous flow apparatus of my own design to be most useful It is provided with a half-gallon bag of thin texture close to the machine and a delicate spring expiratory valve close to the patient This valve is connected by a metal elbow to the tube in the trachea I endeavour to interfere as little as possible with the normal respiratory mechanism of the patient Low pressure is used as a routine, but ample high pressure is immediately available in case of emergency

In every case gauze packing is used to ensure that breathing takes place through the tube and not outside it and also to prevent blood from reaching the trachea It carefully placed around the tube in the pharynx this packing is sufficient for practical purposes In operations upon the nose the gauze keeps the soft palate in close apposition to the posterior wall of the pharynx This method of packing is more effective than gauze or sponges in the post-nasal space, and is less likely to cause discomfort after operation

SUMMARY

1 The fundamental principle of endotracheal anaesthesia is the provision by intubation of an airway that is proof against obstruction

2 High pressure insufflation is usually unnecessary

3 Deep anaesthesia is not essential for intubation

4 Dexterity in intubation minimizes the disadvantages

5 Owing to the greater ease with which intubation can be performed through the nose this route should always be chosen when possible

THE NOSE AND THROAT IN RELATION TO ORBITAL AND OCULAR DISEASE

BY

J LIWIN B S, F R C S,

SURGEON, WEST NORFOLK AND KING'S LYNN HOSPITAL

In this article only such conditions will be described as have their origin and points of attack in the nose and throat The diseases under this heading are all inflammations in which the eye changes, though often the first to appear, are nevertheless only secondary to foci of gross infection in neighbouring structures It is to emphasize and familiarize these important relationships that these notes are put together

Anatomical Considerations

The spread of infection from the nose and throat to the eye may take place along any of the usual channels, but as in one or two important instances such spread is direct, it is necessary to appreciate the anatomy of the parts and, in particular, the anatomy of the accessory nasal sinuses which are grouped round the orbital cavities

The major part of the skeleton of the nose may be regarded as suspended from the base of the skull between the two orbits, and several bones on either side enter into the formation of both structures These bones are the sphenoid, ethmoid, maxilla, palate, frontal, and lacrymal The os planum of the ethmoid forms the largest part of the inner wall of the orbit, and attached to it on the nasal aspect is the lateral mass enclosing the anterior, middle, and posterior groups of the ethmoidal air cells These air cells are incomplete in parts in the disarticulated bone, and in life are closed in by neighbouring structures On the upper surface a few half-cells of the middle group are completed by similar half-cells on the under surface of the orbital plate of the frontal bone bordering the ethmoidal notch The anterior or infundibular cells are completed by the lacrymal bone and maxilla, where they form the anterior part of the inner orbital wall The posterior ethmoidal cells open into the sphenoethmoidal recess where they are opposed to the conchae covering the sphenoidal air sinuses

The anterior ethmoidal artery, though a vessel of no great size, is of considerable importance in the group of diseases under consideration, owing to its anatomical position A branch of the ophthalmic artery, it runs inwards and leaves the orbit by passing with its accompanying vein and the nasal nerve through the anterior ethmoidal canal This canal lies between the cells on the upper surface of the lateral mass of the ethmoid, and is commonly completed by the articulation of the orbital plate of the frontal From this canal the artery emerges on to the cribriform plate lying under the dura of the anterior fossa, whence it runs forwards, and piercing the bone at the side of the crista galli enters the cavity of the nose, where it lies on the deep surface of the nasal bone The antrum of Highmore lies immediately beneath the orbit, and its roof formed by the orbital plates of the maxilla and palate is also the floor of the orbit In its roof is a canal containing the infra-orbital nerve and vessels, the latter joining the parent trunks in the sphenomaxillary fossa The antrum opens into the nose in the middle meatus All the accessory nasal sinuses open into the nose and are at any time liable to become infected from the nasal passages

Orbital Cellulitis

The first condition to be dealt with is orbital cellulitis It is unfortunately true that its relationship to ethmoid or other sinus disease is far from being generally appreciated, yet apart from cases caused by penetrating wounds of the orbit, orbital cellulitis is practically always secondary to inflammation in the ethmoidal cells Its treatment therefore lies essentially in the hands of the nasal surgeon Simple drainage operations on the orbit frequently fail to save the life of the patient, and still more frequently leave a persistent discharging sinus Orbital cellulitis is a complication of acute, but rarely of chronic, sinus inflammation, in spite of the fact that chronic ethmoiditis, characterized often by the formation of nasal polypi, is a very common disorder The reason for this anomaly will be found in the discussion to follow on the mode of spread of the infection

Following the rules governing the spread of infection elsewhere in the body there are three possible routes—namely, the blood stream, the lymphatics, and some direct path There is no suggestion that infection is via the blood stream, except perhaps as a terminal event when a widespread dissemination may take place from one of the larger venous sinuses Spread by lymphatics may also be excluded, as the parts are but poorly supplied with lymph vessels, and there is no connexion demonstrated between the orbital and ethmoidal symptoms

A direct spread is the one that almost certainly takes place, and there are one or two alternative routes even here to be considered A possible route is through the os planum, but although this is a very thin plate of bone, it is fairly tough, moreover, experience in operating on these cases nearly always reveals it intact There is no evidence that, save in neglected cases, it allows the passage of infection

The most probable path is that along the line of the ethmoidal vessels, and there are several points strongly in favour of this view There is a ready-made communication in the ethmoidal canal between the ethmoidal and the orbital cavities The pus found in the orbit in cases of orbital cellulitis is always in the upper and inner part of the cavity—that is, about the opening of the anterior ethmoidal canal Furthermore, the passage of infection by this route accounts satisfactorily for two of the most common and important complications of orbital cellulitis—namely, cavernous sinus thrombosis and meningitis

The mere presence of a collection of pus in the orbit is not in itself sufficient to cause thrombosis of the veins in the neighbourhood, and of the sinuses into which they drain, but such a condition would readily arise as the result of a spread of thrombosis along the radicles and trunk of the ethmoidal vein, which opens into the ophthalmic vein, and so into the cavernous sinus It is worth noting here the parallel way in which cavernous sinus thrombosis may arise from sepsis on the face by spread along the infra-orbital vessels It has already been noted, too, that part of the course of the ethmoidal vessels lies under the dura covering the cribriform plate In this situation the dura is perforated by the olfactory roots, and affords a portal of entry for infection from a septic phlebitis such as obtains in the conditions under consideration Meningitis occurs quite frequently in fatal cases of orbital cellulitis, and is evidenced by intense headaches, and, more typically, by hyperpyrexia

Although the ethmoidal air cells have alone been considered as the starting point of orbital cellulitis, this condition may nevertheless complicate acute infections in the frontal sinus and the sphenoidal sinus, though less frequently Quite often both frontal and ethmoid, or sphenoid and ethmoid, are affected together

The above account is the argument for treating orbital cellulitis by radical operation on the accessory nasal sinus, by the external route Apart from haemorrhage, the result of inflammatory engorgement, the steps of the operation can be followed deliberately and the source of the infection traced and eliminated Briefly, the operation consists in perforating the nasal process of the maxilla and opening up the frontal sinus and the lateral mass of the ethmoid Infected cells are opened and removed as far as possible, and the os planum is cut through to drain the orbital cavity The anterior ethmoidal artery is almost constantly severed Bleeding yields readily to moderate gauze pressure, but the site of the haemorrhage demonstrates very well, in the living, its close relation to the orbit It is important to make as complete a clearance as possible, as infection often starts far back, but the patients are often so gravely ill that complete removal of the lateral mass is not always possible, and one has to be content with ample drainage

Enlargement of the Blind Spot

The second disorder to be discussed is a more purely ocular one It has a fairly high incidence but its relation to primary nasal infection is little appreciated It is first manifested purely as a disturbance of vision, most often unilateral, and there is found a blurring and loss of visual acuity in that part of the retina immediately surrounding the optic disc A most important sign and a fairly constant one, is enlargement of the blind spot for white and colours as determined by perimetric examination This in all probability signifies an inflammatory lesion of the retinal fibres in the affected area The enlargement of the blind spot is known as Von der Hoeve's sign, and is described by him as an important symptom of posterior accessory sinus disease, and where no other cause for the eye changes can be found he considers it an indication for operation on the sinuses Another observer found in 102 patients suffering from ethmoidal and sphenoidal sinus disease enlargement of the blind spot in no less than 31 per cent of cases In my experience, however the antrum is as often at fault A case that came under my care recently illustrates very well how completely unsuspected is this underlying nasal infection

P H was referred to me by my colleague Mr S T Parker to whom I am also indebted for the notes on enlargement of the blind spot The patient complained that for three weeks she had had blurring of vision in the right eye Mr Parker found enlargement of the blind spot and sent her to me for examination of the nasal sinuses There was nothing in her history suggestive of sinus disease and examination of the nose only revealed a marked deflection of the septum to the left There was no trace of pus in the nose or nasopharynx A skiagram however revealed a marked opacity in the right antrum and exploratory puncture under local anaesthesia found thick mucopus Under a general anaesthetic I drained the antrum into the inferior meatus by the intranasal method A considerable amount of pus was evacuated at the time and some discharge persisted for several days after the operation No organisms could be grown from the pus on ordinary media

In two weeks there was marked improvement in vision in the affected eye and a month later it was almost completely restored only a slight deficiency being recorded by the perimeter

While the connexion between ocular disease and sinus disease is certain, the path along which the infection travels is not so clear It is presumably a direct one, both parts being almost always affected on the same side It is probable that the ocular element is not in fact an infection but the result rather of compression by inflammatory exudate at the back of the orbit The latter assumption is supported by the rapid improvement which follows adequate treatment of the primary nasal trouble In a number of cases no direct evidence of sinus disease can be found but frequently there is a history which indicates some such trouble perhaps months before One girl had pain and swelling in one side of the face with profuse discharge of pus from one side of the nose following a bathe in a well patronized swimming bath I have no doubt she had an acute antral infection, yet her visual defect only became apparent some six months later I have found a similar coincidence in other cases and it appears that sometimes at any rate the progress of the trouble from the nose to the optic nerve elements is so slow that the original focus may have cleared up before the advent of the eye symptoms

Phlyctenular Conjunctivitis and Blepharitis

The third and last group to which I am going to refer includes cases chiefly in children of phlyctenular conjunctivitis and blepharitis Although they almost always come for treatment via the ophthalmic department children frequently attend the throat clinic for recurrent sore throat and complain that each attack is associated with inflammation and soreness of the eyelids These cases are often intractable to all form of local treatment as they are secondary to a remote focus usually in the tonsils The result of tonsillectomy in this disorder are so uniformly good that the operation should be undertaken even in the absence of any apparent tonsillar disease The tonsils should be removed by formal dissection

One or two points of interest come out in the examination of the tonsils in these children They are quite frequently very small and look innocent even on section after enucleation Further there is most often a complete absence of palpable gland in the neck and this is the more striking as the vast majority of children presenting themselves at the throat clinic have some cervical adenitis

In the absence of any demonstrable anatomical connexion it must be assumed that the tonsils in these cases contain some toxin which circulates in the blood stream and lowers the vitality of the conjunctivae, which are already infected from purely local sources Any effective resistance is thus hampered, and the condition becomes chronic

I have not attempted in these notes to describe in any detail the symptoms and treatment of the diseases enumerated My purpose has been solely to draw attention to relationship which must be fully appreciated in order to provide the scientific treatment so essential for cure

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL

THE TREATMENT OF TETANUS

While the prophylactic dose of antitetanic serum has tended to make the incidence of tetanus an increasing rarity, it may still happen to anyone to have to treat a case and the problem of the correct treatment suitable to various cases must be approached through the accumulated experience of the few instances available The treatment of the wound by thorough disinfection is the first consideration, and, if suitable complete excision is indicated Where excision is impossible then continuous irrigation with oxygen producing agents may prevent the production of any additional toxins

For the control of the spasms the injection into the spinal canal of hypertonic salt solution, after removal of cerebro-spinal fluid will give approximately twenty-four hours' remission of symptoms Under chloroform anaesthesia about 10 c cm of cerebro-spinal fluid is removed slowly and 2 c cm of 25 per cent magnesium sulphate solution in distilled water is injected To overcome the effect of those toxins already exerting their harmful influence massive doses of antitoxin should be given This may be administered by subcutaneous intravenous or intrathecal injection preferably by all three methods I have used with success in an adult case injections of 10 000 units into the spinal canal after removing a similar amount of fluid, as an initial dose, and injections by intravenous and subcutaneous route of the same dose as well making 30,000 units in all These measures may be repeated more than once, at daily interval if there is an increase or so long as there is no abatement of the severity of the symptoms of spasms and trismus etc

Experience gained with adults during the war does not afford any guidance in dealing with tetanus in children and as there are so few cases in which the treatment and dosage are on record I am venturing to record the result I obtained in a recent case showing the dose used and the unusual reaction observed afterwards

A medium-sized boy aged 12, had a lacerated wound of the left leg 5 inches long transverse to the long axis as a result of falling from a tree on April 5 th The wound was dressed and treated with boric fomentations but became septic On April 15 th he was seen by a colleague who observed a well marked condition of trismus with stiffness of the back I saw the patient with him later in the day and removed the boy to hospital

After admission under general chloroform anaesthesia the wound was thoroughly inspected and cleaned and it was found to extend throughout its length 3 inches from the skin edges into the subcutaneous pace Carrel Dakin irrigation was then arranged from the most limit of the infected area and the wound was dressed with gauze soaked in hydrogen peroxide solution The healing of this presented no unusual features After dealing with the wound lumbar puncture was performed and 10 c cm of fluid was drained and an injection of 5000 units of antitetanic serum given 6000 units were given by subcutaneous injection

On April 16th the general condition of the boy was as above no spasm had occurred but the trismus and the general stiffness of the back were unchanged An intravenous injection of 7000 units of antitetanic serum was given and an injection of 1/6 grain of omnopon was sufficient to allay the pain in the back On

April 17th another intravenous injection of 7,000 units was given The trismus was unchanged, but the stiffness and pain in the back were less marked and were easily controlled by omnopon On April 18th the trismus condition was noted to be relaxing, and gradually became less day by day On April 26th the patient suddenly commenced to register a temperature of 103° F, but complained of no symptoms or malaise, and no signs of any trouble could be found in any of the organs This high temperature remained unchanged day and night until May 1st, when it fell by lysis Throughout this period the patient felt perfectly well He was discharged from hospital on May 10th

I admit that this case must be regarded as an exceptionally mild one, but the following are points of interest

1 Thorough irrigation with the Carrel Dakin method can prevent the development of any further tetanus toxin when excision of the wound is impossible

2 Massive doses of antitetanic serum should be administered as soon as possible, in the case of a boy those given proved efficacious and safe

3 The reaction from antitetanic serum may take the somewhat unusual form recorded

4 The injection of hypertonic salt solution was not required in this case, but I have used it in the severer type of case with most satisfactory results in relieving spasms, and I can strongly recommend it

A PARASITIC DERMOID CYST

THE following clinical details of a case of dermoid cyst with no obvious connexion with an ovary appears to be worth recording, in view of the migration which would seem to have occurred

A multipara, aged 44, was sent to me by Dr Speight of Burscough She had backache and a "bearing down" pain, neither of which was relieved by rest The symptoms dated roughly from her third confinement She had had five labours, all of which had been normal and followed by normal puerperia Examination revealed a slight degree of vaginal prolapse, and the presence of an irregular hard mass behind the uterus This mass was considered to be either a calcified fibroid or a *lithopaedion*

At operation the omentum was found to be lightly adherent to the abdominal wall, the mass was situated in the pouch of Douglas where it was embedded in adhesions These were easily separated and the mass was shelled out, it was completely within the peritoneum The left appendage was normal, but the right was represented by a small tubo ovarian cyst The specimen, when removed, was completely enveloped in a calcareous wall, and was 7½ cm long On opening a window in it sebaceous material and hair were seen

The point of interest about the cyst is its origin Since it lay within the pouch of Douglas, it could not be an extraperitoneal dermoid, and the fact that it was buried in adhesions and had no pedicle suggests that this was not its original site The calcareous change in its wall supports this view, for it implies a deficient blood supply

The common site for a dermoid tumour anywhere in this neighbourhood is certainly the ovary Assuming this, three possible modes of origin may be considered (1) From a supernumerary ovary As there was no sign of any 'ligament" running from the tumour to the uterus or inguinal canal (no remnant of a gubernaculum ovarii) this origin can be dismissed (2) From accessory ovarian tissue Had it arisen thus it would, in all probability, have been extraperitoneal (3) Separation from the ovary in which it grew, probably by torsion of its pedicle This appears to be the most likely explanation, the condition of the right appendage and the presence of omental adhesions are in favour of such a suggestion Unfortunately, no sections were cut from the right appendage to determine whether any ovarian tissue was present

Complete separation of ovarian dermoids from their point of origin appears to be of infrequent occurrence It is mentioned by Senn[1] and older authors, but it has only been possible to trace a few specific cases in the literature Spencer Wells[2] records a case, and refers to one reported by Atlee Doran[3] notes a case described by Knowsley Thornton, in this patient one ovary was cystic and the other was represented by a short tag of fatty and partly calcareous tissue Heimann[4] had a case in which, at the time of operation, both ovaries were intact, he considered that this tumour arose in an accessory ovary This case is complicated by the fact that the tumour was in part pseudo-mucinous and in part dermoid Remprecht[5] reported a case, but does not give sufficient details of the appearance of the ovaries at the time of operation Ernest Herman[6] appears to have had a case, and to have operated during labour, but the description leaves the reader somewhat in doubt Miss Ivens[7] has reported a case in which the whole ovary was involved, and its previous existence represented only by a scar on the back of the broad ligament Miles Phillips's case[8] was very similar to that of Miss Ivens In Dartigue's case[9] the separation involved the whole appendage, and the tumour represented both tube and ovary

It is noteworthy that where parity is mentioned the women were all multiparae, and that where the side is specified the right is the commoner Pregnancy predisposes to torsion of the pedicle of ovarian cysts, and the normal obliquity of the pregnant uterus may cause it to have more effect on right-sided cysts

GLANDULAR FEVER IN THE FALKLAND ISLANDS

A SHORT note on an epidemic of glandular fever that occurred in 1926 in a very isolated community may be of interest The cases numbered 87—52 males and 35 females The incidence in the sex and age groups is shown in the following table

Age Group	Male	Female	Total	Percentage
Under 5	5	2	7	8
5–15	9	8	17	20
15–25	22	11	33	38
25–45	11	10	21	24
45–65	4	4	8	9
65 and over	1	—	1	1

The youngest person afflicted was a boy aged 2 years, the oldest a man of 70 The disease was characterized by the sudden onset of slight soreness and redness of the throat, difficulty in swallowing, and pain in the neck, accentuated by movement Fever was present in all cases, the temperature ranging between 100 and 103° F Painful bilateral adenitis of the neck appeared between the second and fourth days of the disease The glands varied in size from that of a pea to a hen's egg, and were of a stony consistence In eight cases the onset was very acute, with marked headache, nausea, vomiting, and prostration In two cases the onset was marked by severe epistaxis At an early stage of the disease five cases showed a nephritis of a mild type associated with pain in the lumber region Recovery in all cases was uneventful Four cases developed retropharyngeal abscess One of these, a female aged 30, died owing to the sudden rupture of a large retropharyngeal abscess causing rapid asphyxia In a boy, aged 8, the cervical adenitis went on to suppuration, and a large quantity of pus was evacuated on incising the affected gland One patient only, a man of 29, showed a slight enlargement and tenderness of the spleen and liver The average duration of the disease was about a month Careful nursing and the administration of small doses of calomel was the method of treatment

In isolated communities the lack of resistance to infectious disease and its incidence in age groups is of interest Old and young alike have little immunity to the

so-called diseases of childhood It has been my experience in a community where infectious diseases were previously unknown or a mere legend, that the maturer people are as liable to infection as and suffer more acutely than, the young During this epidemic of glandular fever all the complications of the disease occurred in the third, fourth and fifth age groups, with the single exception of *the boy* who e adenitis went on to suppuration

Among several recent immigrants men of the third age group from the South of England, none of whom gave a history of glandular fever, only two contracted the disease, although all without exception lived in precisely the same manner and in close as ociation with the natives of the island among whom the case incidence of the disease was very high

Reports of Societies

SOME AMPUTATION PROBLEMS

At the meeting of the Section of Orthopaedics of the Royal Society of Medicine, on November 4th, Mr P Jenner Verrall delivered the annual address from the chair on "Some amputation problems" after which he invited discussion The discussion was a continuation of one held in the Section of Surgery in April last (*British Medical Journal*, April 12th, p 693)

Mr Jenner Verrall said that he proposed to deal in the main with the unusual, but he wanted first to state briefly what was the normal and ideal Speaking of the lower limb he said that a tilting-table prosthesis was to be avoided if possible but it must be fitted for a stump of less than 5 inches measured from the great trochanter An above-kn amputation should be at least 4 inches above the condyles and preferably should leave a stump measuring 10 to 11 inches where the normal femur measured 19 inches, or 12 inches if the femur was longer The ideal below-knee stump contained 7 inches of tibia Flaps should be no longer than the diameter of the limb and should contain no more muscle in their base than was needed as sheer tissue solely to ensure the blood supply He expressed himself against alcohol injections into the nerves they produced a perineural fibrosis which was bad in the long run Haemastasis should be most complete, and there should be no hesitation in surrounding small portions of tissue with a circular ligature if there were small vessels which could not be picked up singly Haemastasis being complete, he would advise that no drainage be employed He would far sooner stitch up loosely, allowing space between stitches for oozing than introduce a drainage tube which, like other doors could be passed through in both directions Massage where the stump was normal was quite useless, and might be harmful as militating against rest and settling down Re-amputations were more difficult than primary ones owing, among other causes to the pre-existing scar, also the congested and varicose condition of the parts Of the three varieties of emergency amputation, guillotine, through-joint and amputation with flaps left open, the last was rarely used and he thought the first superior to the second Undue retraction of the skin would be prevented by some form of extension such as the admirable method described by Elmslie If pus pockets were found in a case for re-amputation although they might be quite sterile on bacteriological examination, it was not fair to take the risk and re-amputation must be put off One would always tend to err on the side of waiting too long and it often happened that while waiting the amputation would heal and even the nerves which had been cut short at operation give no more trouble

Mr Verrall then proceeded to give his opinions on certain amputations Beginning with the foot he pointed out that one disadvantage of the Lisfranc operation was the loss of one arch of the foot and with regard to the Chopart amputation he gave certain reasons why it was a bad one in the adult Coming next to the Syme by which he meant the modern Syme with the elliptical incision he would not deny the existence of many successful Symes, in both civil and military cases, but the Syme was far less certain of remaining perfectly satisfactory than was the mid-tibial amputation It had been said that an unsatisfactory Syme was a Syme badly done, but he had seen many Symes go wrong which had been performed by surgeons whose skill was beyond question It was generally admitted that a mid-tibial amputation should leave a 7-inch tibia and a slightly shorter fibula In a muscular and well-nourished leg an anterior skin flap was good, but in atrophic legs, especially with old sciatic injuries, where the circulation was none too good he preferred to make a postero-external flap, calculating the length so that after shrinkage the scar would lie transversely half an inch below the tibial level The Stokes-Gritti amputation was still spoken of in literature as a good operation but in his experience it was not and Mr Muirhead Little had very kindly allowed them to borrow from the Royal College of Surgeons an admirable portfolio of x rays and other pictures from his collection, which to the speaker's mind showed every sort of misbehaviour of which the Stokes-Gritti was capable Dealing with unsatisfactory stumps in general, Mr Verrall declared that much trouble was caused by too early limb-fitting In a perfectly clean amputation, where sepsis had never been present or had been prevented from developing the fitting with the prosthesis might take place within three months but in war cases and secondary amputations in civil life six months should be allowed to elapse Below-knee pylons were very unsatisfactory, and above-knee pylons though surgically bad, were economically good But the pylon must be fitted by a limb-maker under surgical supervision, reproducing the pressure points which would remain in the permanent prosthesis to be fitted later Coming to the problem of stiffness of the joints he said that in the case of the hip, ankylosis in good or bad position was almost an absolute bar to the fitting of a satisfactory limb The alternatives were either to re-amputate to give the best stump for the tilting-table or to attempt the formation of a mobile joint As no weight had to be borne on the joint it would appear that a simple excision of the hip would suffice, but this was not satisfactory in his experience because the patient had no control over the prosthesis it was the fulcrum that was lacking Arthroplasty of the hip in amputation cases was excellent—more promising in stumps than in complete limbs A hopelessly flexed hip should be left flexed and the stump shortened to allow of the fitting of a tilting-table The longest stump that could be so fitted was one of 6 inches this was very unsightly With regard to the treatment of neuromata this was less and less important Indiscriminate removal of neuromata was to be deprecated Operations for a painful neuroma should be local Circulatory defects in stumps were commonly due to excessive length or excessive volume of soft tissues They might also be due to deep seated circulatory defects In certain stumps there was a vascular upset, nervous in origin and exceedingly difficult to cure He was more and more convinced that necessary re-amputations which one saw in so many of these cases were harmful and he refused to do them Time and occupation were the only cure The phantom limb was a simple problem operations were to be avoided and if the phantom were considered as definitely due to a neuritis syphilitic or alcoholic or other it was important to alter the line of treatment and to defer limb-fitting for a long period while the case was treated Mr Muirhead Little had mentioned the existence of pain felt in the stump during defaecation and micturition This was not uncommon and the reverse was often found—pain in the rectum or bladder when the limb was worn This was due to unstable nervous reflex Time again was the only cure though in some cases pain was due to imperfect limb-fitting Since the war there had been two admirable works on the operative side published in this country—namely, Lane's on "Amputations" in Carson's *Modern Operative Surgery* and Muirhead Little's *Artificial Limbs and Amputation Stumps* The developments up to this date were an alteration in opinion as to the length of the thigh stump the value of the Syme and of the Stokes-Gritti the question of drainage in amputations of treatment of the nerves a consideration of the choice in the case of mid-tibial

amputation between an anterior and a posterior flap based on the trophic condition of the leg, and, finally, the admission of the operation of arthroplasty as a reasonable and eminently successful proceeding for the treatment of stiff joints in amputation stumps

Mr E MUIRHEAD LITTLE said that it was a matter of congratulation to him to find that the decisions generally agreed upon at Roehampton at the end of the war on various points connected with amputations had nearly all been upheld He found himself in agreement with Mr Verrall on almost every point As to the Syme amputation, he was still rather unrepentant, but it was of no use gainsaying positive facts Mr Verrall and others who had been practising since the speaker left Roehampton had found positive difficulties with the Syme There were many Symes which were excellent, a good Syme was excellent, a bad Syme was worth nothing In this connexion he reminded the section of Martin Huggins's book, *Amputation Stumps Their Care and After-Treatment*, in which he had laid down an excellent way of treating the flaps of the Syme after operation or dressing With regard to the Stokes-Griffith amputation for the knee, the evidence which he had brought up for exhibition to the meeting showed how bad the results could be In a case which it was intended should be fitted with a tilting-table, he quite agreed that the best thing was an amputation through or just below the lesser trochanter, giving the patient something more than the bare pelvis on which to sit With regard to *stiff joints*, he quite agreed with Mr Verrall, as also in his observations about the uselessness of the limb when the fulcrum had been excised away

Mr R C ELMSLIE said that he was still unrepentant with regard to the Syme He believed with Mr Little that a really good Syme was a good amputation, though he appreciated that the limb-fitting was a difficult matter One must not condemn any amputation too loosely There was one amputation which he supposed most of those present would condemn—namely, amputation through the knee-joint—yet he must plead guilty to having done it on at least three occasions in recent cases In each of these cases he was amputating over a congenital deformity in which the tibia was missing, and the children had been accustomed to get about on the flexed knee, so that they had an absolutely perfect end-bearing on the condyles of the femur Although one might condemn an amputation generally, one must not wipe it out as a thing never to be done

Mr W R BRISTOW said that there were plenty of Symes which remained good for a year or two Only this week at St Thomas's he had had to deal with the case of a woman on whom seven years ago a double Syme was done Her stumps remained good for five years, but between the fifth and seventh years the end of one stump became rather loose and began to give trouble The procedure was followed which Huggins practised in 1918, and re-amputation was done straight away With regard to the treatment of nerve ends, it was the small nerves which gave the trouble—the internal saphenous in the thigh and the internal cutaneous in the arm It was often expedient to shorten these nerves, crush them, and perhaps put a ligature on them With regard to arthroplasty, he recalled that it was at Shepherd's Bush that he did the first arthroplasty of the hip-joint on amputation stumps He remembered one case with double ankylosis of the hip, and two short thigh stumps Sir Robert Jones agreed that an attempt at arthroplasty was the only expedient His experience agreed with Mr Verrall's that the arthroplasty where some fulcrum was retained was very useful in the limbs and particularly in the hip

Mr ROCYN JONES recalled that when he had the honour of assisting Mr Muirhead Little it was the invariable custom to inject the nerves with alcohol He thought this was valuable in emergency amputations where a primary amputation had to be done through possibly a very bad fracture, and later it might be necessary to do a secondary amputation It certainly did diminish the shock of the operation very considerably Particularly in a high amputation through the thigh, an injection into the sciatic nerve was of some value

Mr S L HIGGS agreed with Mr Verrall's point about refraining from putting in a drainage tube except in very rare instances

Mr VERRALL, in reply, asked whether orthopaedists were to teach that the improved Syme was a good thing and that the surgeons who performed it could hold out reasonable prospects to their patients that it would be a permanent amputation He had seen a certain number of good Symes, but one had to legislate for the majority, and he felt that the chances were against getting a permanent satisfactory condition with the Syme As to crushing of the nerves, that was an expedient he believed in, but pulling down and shortening were procedures with which he could not agree, he was sure that the effect was to produce perineural fibrosis

AIMS AND LIMITATIONS OF SURGERY

IN the Section of Surgery of the Royal Society of Medicine, on November 5th, Mr C H FAGGE delivered an annual address from the chair which was probably the shortest on record Its delivery occupied only a quarter of an hour, and at the close Mr Fagge invited discussion

Mr Fagge began by saying that the philosophic surgeon would admit that his ideal—the restoration to the normal—was never accomplished Much of the surgeon's time and energy was taken up in attempts to prolong life in patients suffering from terminal states, for whom his best endeavours could do no more than leave them in a condition far short of normal In truth, far too much of modern surgery was mutilation Excluding the correction of some injuries, such as fractures, and cosmetic operations for congenital deformities, such as cleft palate and hare lip, there was little in the surgical technique which *did not replace one evil by another, admittedly of less and usually of unimportant degree* The fascinating field of surgery which endeavoured to combat the ravages of age by transplantation of an organ or part of it from an ape closely allied to man, or to replace a damaged or diseased organ by a similar organ taken from another human, or to fill a deficiency such as an absent finger by grafting another in its place, was still in its infancy It was clear that much that had been exploited in this direction could not bear the scrutiny of judgement by results Such graftings and transplantations could only be successful when the technique of connecting the blood vessels of the transplanted viscus to those of the recipient had been improved to a degree not yet possible, so that immediate restoration of the necessary nutritive fluids could be established with a reasonable degree of certainty This restoration of circulation applied not only to blood vessels but also to the lymphatics

Passing to the physical limitations by which the surgeon's work was hemmed in, Mr Fagge confined himself to those which resulted from the nature of bodily tissues and from the healing of the operation wound Lord Moynihan had remarked that surgery as a craft had reached finality That idea was not new, in an American journal there recently appeared a quotation to the same effect from Erichsen, made at a time when Listerism had become firmly established But if the half-truth were admitted, so must the reservation that even with the very best technique the finest and most accurate primary union resulted in the formation of a scar Modern aseptic technique had undoubtedly modified the amount of scar formed in any tissue operated upon by limiting the leucocytic infiltration, but it was generally believed that proliferation of the fixed connective tissue cells was the ultimate factor in the causation of fibrous tissue, and, so far as he knew, there were no means to hand by which this might be controlled What happened to any one of the higher connective tissues when it was subjected to an abnormal strain? When applied to the soft parts, a strain, in his judgement, usually resulted in the suture material, of whatever nature or strength, cutting through, with the giving way of the structure which it was desired to hold down, or in the formation of a scar by degeneration of the tissue held down This limitation appeared to apply to

many of the operations described under the name of "pexies", a particular example which illustrated his point was that of orchidopexy The consideration of such behaviour of soft parts under strain brought him to another type of technique—namely, operations for incisional or ventral hernia Here an area of scar had been produced by infection, and the fibrous tissue over this area offered a feeble resistance to normal abdominal tension The normal resilient elastic abdominal wall had been replaced by an inelastic scar This was spoken of as stretching but in fact it gave way and a gap resulted The object was to replace the scar by normal resilient muscular layer Many operations had been devised and much ingenuity expended in attempting to close this defect, and yet the majority of such devices could only replace a thin weak scar by a thicker more resistant one Such was the method of action of metal filigrees or the introduction of living suture material, after the method of Gallie and Le Mesurier In dealing with such cases, the speaker submitted, the surgeon should concentrate attention not on the gap, but on the tissue which filled it, beginning with a free excision of all abnormal fibrous tissue scar The surgeon's heart must be hardened and his courage steeled, for a most alarming gap would be left When this had been done, normal aponeurotic and muscular layers could be approximated safely and it was all important to spend time in accurately defining the layers of the abdominal wall and suturing them one by one He had not so far met any incisional or ventral hernia which he could not close in this way with ordinary catgut sutures, and an inquiry made by his former registrar of patients dealt with in this way had revealed no recurrence, all the patients were following their normal occupations without pain or the use of appliances Finally, he spoke of keloid, an interesting eccentricity of scar formation He remembered observing, thirty years ago that after an operation for inguinal hernia in small children, if the incision encroached on to the hair-bearing pubes that part of the scar might be keloid, and the rest a thin normal scar In a patient operated on recently the cholecystectomy scar was keloid above and below but normal in the middle It was Mr Fagge's belief that keloids, if excised freely, did not re-form

Mr C Max Page thought that Mr Fagge had been a little too pessimistic in describing almost all the performances of the surgeon as mutilation After all, Mr Fagge himself had referred to hernia, and that surely was very definitely an operation which restored to the normal, or nearly so He thought bone-grafting might be placed in the same category, though it was quite true that not a great amount of it was done He confessed that his own practice in the treatment of ventral hernia differed from that which Mr Fagge had laid down In the cases in which there was a large gap he had usually done a plastic operation, generally without the use of foreign material such as filigree or living suture and had attempted to get apposition of the main bulk of the abdominal wall by an overlap such as was practised in the Mayo operation for umbilical hernia He might be wrong but he believed he could show quite as good results by that method though he had had no registrar to collect them for him With regard to keloid, he had always thought that if keloid were excised another keloid formed He regretted that Mr Fagge had not touched on infective processes

Mr V Zachary Cope said that it was always interesting and encouraging to hear the philosophy of a surgeon Limitations of surgery might be dealt with from several points of view—for example the limitations to which the individual surgeon was kept by the multiplication of specialties There was a tendency for the individual surgeon to become limited to one small sphere In surgery itself there could be no limitation *It it was to live it* must advance When Brodhsen said that surgery had reached finality, the kidney the brain the spinal cord, and most of the internal viscera had not been operated on, but now it could be said that practically every viscera, from the pituitary body to the remote depths of the spinal cord was dealt with by the surgeon But he thought that surgery would advance by co-operation in a more intelligent manner with the physician. In surgery there might come about, if one liked to call it so, a retrogression, which was really an advance, in the sense that operation would be avoided in a greater number of cases, and more cases would go to the physician He saw no reason for example why a medical cure should not be found for exophthalmic goitre, and in gastric ulcer and suchlike conditions there should be found some method of cure without operation He would not call that a going back of surgery it was an advance of the whole of medicine In the case of scars Mr Fagge had said that it was impossible to have a cut without getting some scar But it was well to remember that in the modern treatment with radium there was no scar in the usual sense of the term, or the scar was infinitesimal, and the tissue left was practically normal in appearance It was possible that in the next few years, by the suitable application of radium or radiotherapy of various kinds a disappearance of scars might be obtained and a reappearance of normal tissue Many keloids became softer under x-ray treatment

Mr A J Walton said that the surgeon must feel more and more, as he looked back upon his results that the aims and objects in view were to abolish surgery entirely Practically everything the surgeon did was of course a mutilating operation But, fortunately every individual was born with a pretty big banking account and was able to go on for a long time until the balance was exhausted He had always laid it down that in surgery as small an amount of normal tissue as possible should be removed He agreed with Mr Cope that surgical treatment of exophthalmic goitre was absolutely wrong, but unfortunately to-day it was the only method of certain cure In the same way with the surgery of the stomach the more modern Continental method of removing seven-eighths of the stomach for an ulcer perhaps only half an inch in diameter was certainly wrong In his own private practice he found himself doing more and more medicine and less and less surgery Perhaps the most ideal operations for the restoration of normal function and anatomy were those for the removal of benign tumours and next to these came operations for restoration after accidental lesions Fractures had been mentioned and there one did restore very nearly to the normal with the minimum of scar tissue With regard to infective processes in no field did the surgeon feel so absolutely hopeless One factor he could not control was the presence of sepsis If an appendix for example could be dealt with before infection had spread the focus could be removed and everything was plain sailing But once the condition went beyond that, and the infection spread there was little more that the surgeon could do He agreed with Mr Fagge as to the treatment of ventral hernia His own experience was that with careful dissections and working out all the layer one by one there were very few hernias where one could not restore completely by sewing up the separate layers There was one exception to this—namely where a hernia had arisen through paralysis of muscle Where there was a destruction of the lower section of the rectus muscle or wide paralysis of the oblique muscle, it was, of course almost impossible to restore

Mr Eric Lloyd asked whether the president's philosophy extended to offering any explanation of the curious variations which most of them had observed in patients suffering from congenital abnormalities of various kind In particular, he was thinking of the children one sometimes saw who had just escaped a hare-lip All surgeons had seen such patients with scars which nature had produced, and which they attempted in vain to emulate Why was it that nature could produce such a superior scar to anything their best effort could accomplish Indeed that point might be carried further for every individual face was made up of most marvellously united seams He had been struck by the occasional occurrence of keloid at the lower end of an inguinal incision His impression was that this occurred more frequently in the lower end of a hernial scar than in the upper With regard to treatment of keloid he believed the proper method was not to apply x rays or radium immediately but to excise the keloid and then to apply the ray

Mr Julian Taylor said that anyone who had attempted to operate on a strangulated hernia through a filigree

would hesitate before putting another filigree in He joined issue with Mr Walton on the question of hernia due to nerve injury It was extremely rare for hernia of the abdomen to be due to nerve injury, and the average case which presented a paralysis of the muscle was no exception to the rule laid down by the president

Mr Hugh Lett criticized the pessimistic outlook of the president He did not consider that, after all, surgery was in such a very bad way It was true that the operations might be regarded as mutilating, but what about the disease for which they were done? If one removed a gall-bladder which had given the patient pain and discomfort, and the patient was restored to a state of normal health, even though he had lost the gall-bladder—a loss of which he was quite unconscious—to what extent was he worse off?

Mr Fagge, in reply, said that he had not felt competent to speak about the treatment of acute infections, nor did this part of the subject come strictly under the text which he had taken In reply to Mr Walton, he (Mr Fagge) had, perhaps fortunately, never had a hernia which had arisen through paralysis of muscle With regard to keloid formation, it used to be said that keloid indicated tuberculosis, but it had been his experience that keloid varied greatly with the patients, some patients producing it very easily indeed and others much less easily

CARDIAC PAIN

At a meeting of the Brighton and Sussex Medico-Chirurgical Society, on November 6th, with the president, Mr H Nethersolf Fletcher, in the chair, Dr Donald Hall read a paper on cardiac pain

Dr Hall divided his subject into two groups, according to the pain being non-coronary or coronary in origin The first group comprised a miscellaneous selection, the patients in most cases not having cardiac disease It included dyspeptic pain referred to the heart and not to the stomach, the pain met with in 'D A H,' hyperthyroidism, and other types of functional tachycardia pain occurring in the cardiac region during the course of, and in convalescence after, the acute fevers, and two special forms of heart disease in which pain might be a prominent feature—namely, acute pericarditis and mitral stenosis In this group the location of the pain was mammary or submammary, and not retrosternal It was frequently accompanied by local tenderness, might be present throughout the day and yet the patient be carrying on his or her ordinary vocation, and radiation, if present, involved the entire upper limb, and not merely the ulnar border Apart from tachycardia, with the exception of pericarditis and mitral stenosis, clinical examination of the heart afforded negative results, as did radiography and electrocardiography The second group comprised coronary thrombosis and angina pectoris Although there was a clear-cut difference between the cases of acute coronary infarction and the more chronic cases of the effort syndrome, intermediate types were met with both clinically and in the curves of the electrocardiogram Apart from the rare incidence of coronary embolism, these two types were different expressions of the same pathological process, in the one instance abrupt occlusion of an already diseased artery followed by the sudden ischaemic necrosis of a limited area of myocardium, in the other a slow, diffuse myocardial degeneration produced by chronic progressive atheroma of the coronary arteries Advanced myocardial change might be present without any change in the heart sounds, borders, or rhythm, or any alteration in the blood pressure even if the electrocardiogram was also unchanged, the clinical symptoms of the effort syndrome were so clear that on them alone the diagnosis must be made and maintained Lantern slides were shown of the 'plateau-curve" and subsequent changes met with in coronary thrombosis, and of various abnormalities of the electrocardiogram found in cases of angina pectoris Dr Hall said he had seen typical RS–T deviation shortly after acute pulmonary oedema and cardiac failure in a high did not regard this abnormality *per se* as proof of coronary infarction Serial electrocardiograms are required to make the diagnosis complete

of great value in assessing the recovery of the myocardium The etiological significance of defective blood supply in the effort syndrome was made even more clear by the interesting type of angina pectoris met with in Addisonian anaemia where, although the vessels were intact, anoxaemia and degeneration of the heart muscle were brought about by faulty quality of the nutrient fluid

SPEECH DISORDERS OF CHILDHOOD

At a meeting of the Liverpool Medical Institution, on October 23rd, Dr Barton Hall read a paper on the speech disorders of childhood, with special reference to congenital auditory imperception

Dr Barton Hall said that the importance of the subject arose from the fact that speech disorder was of common occurrence, and that it was often the predominant feature of conditions which were, in their nature, extraordinarily diverse The disorder might be localized to the motor or the sensory sides of the speech mechanism, or to the intellectual processes concerned in speech From the motor aspect the most obvious difficulties arose in cases where there was organic defect in the mechanism of articulation Probably the most common speech disorder to be encountered was that of inco-ordinate speech, stammering or stuttering Although stammering was often classed among the so-called "functional" disorders of the nervous system, it had always appeared to the speaker to be some inherent disability of the patient's higher speech mechanism Lalling and lisping constituted two further disorders of speech The latter was of fairly common occurrence, but lalling was rare in children who had passed babyhood, and might be of so severe a degree as to amount to idioglossia Although the difficulty in idioglossia was that of the correct formation of sounds, the defect was really one of audition Dr Barton Hall then considered the condition known as congenital auditory imperception The literature on this subject was reviewed, particular attention being paid to the subject of pathogenesis, and the lecturer then described three of his own clinical cases in detail, the first, a case of idioglossia in a girl, aged 5, in which there was a definite familial factor, the second, a case of auditory imperception in a girl, aged 7, in which there was a definite familial factor, and the possibility of a traumatic factor associated with an attack of whooping-cough, the third, a typical case of congenital auditory imperception in a boy, aged 8½, who had been diagnosed as mentally defective, and in whom there was a possibility of a familial factor, and also the chance of some birth trauma having occurred The importance of assessing the intelligence in such cases was stressed, and emphasis was laid upon the assistance that such measures gave to diagnosis, prognosis, and treatment

Mrs Barton Hall described the methods employed in assessing the intelligence of these three children, pointing out the significance of using "performance material" in conditions such as auditory imperception, where verbal methods of testing were impossible Examination showed that the intelligence quotients in the three cases were 104, 114, and 94 respectively, all three children proving to be of average, or above average, intelligence

Dr Norman B Capon referred to the many difficulties of examining the sensory reactions in very young children He pointed out that in certain circumstances it was possible to obtain help from the application of conditioned reflexes In regard to the etiology of congenital auditory imperception, prematurity and intracranial birth injury might be concerned, but the evidence was still indefinite

Mr John T Morrison read a paper entitled "A simple method of intravenous local anaesthesia" The technique employed involved the use of one tourniquet and one needle puncture only He then commented on the actual type of anaesthesia produced, and offered some explanation of the possible mode of action of the drug novocain A brief summary was given of experimental work dealing with the "fixation" of novocain in the tissues and its application to surgery In the following discussion it was suggested that since the injection was made in a portion of the

high remote from the tourniquet and the circulation was arrested the anaesthesia might be due to pressure on the nerves by the tourniquet, since it was present in the region of this constriction

FIBROID DISEASE OF THE UTERUS

AT a meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland on October 24th with the president DR A H DAVIDSON in the chair, DR NIVIAN JACKSON showed a large myoma which had been removed from a patient aged 48. The clinical history was as follows:

The patient's menstrual period had been regular but rather profuse. Her appetite was good and the bowels regular. The abdomen was found to be filled by an apparently solid tumour which was shown by bimanual examination to extend into the pelvis. A probable diagnosis of malignant ovarian tumour was made and the abdomen was opened. It was then found that the uterus was attached to the side of the tumour at the level of the umbilicus. The growth was eventually removed with considerable difficulty owing to it being impacted in the pelvis.

The shape of the tumour had been apparently influenced by its growth following the line of least resistance, and extending downwards into the pelvis as well as upward in the abdomen. Microscopical examination showed that its structure was that of a simple fibromyoma with hyaline and mucinous degeneration; no evidence of malignancy was obtained. The weight of the tumour was 15 lb. 12 oz. After the removal a very large raw area was left, and peritonization of the pelvis could only be performed very roughly; the abdomen was closed, and the patient had a normal convalescence.

The PRESIDENT commented on the way this growth had spread; it was the largest myoma he had ever seen, and in view of its size it seemed rather extraordinary that there had been no constipation. In removing large myomata the ureter always involved some difficulty, and in the present case the successful excision was a matter for congratulation. DR R. M. COPEET mentioned two cases of myoma which he had recently seen; in each the growth had weighed about 10 or 12 lb., and neither had given rise to any symptoms.

DR BETHEL SOLOMONS remarked that isolation of the ureters was an essential step in the procedure of removing such large fibroid tumours. He then exhibited two fibroid uteri removed from women during the active child bearing period. They showed hyaline degeneration with some evidence of active growth. In the first patient, who was 47 years old, had been married for twenty-three years and was a 17-para, the only symptoms had been backache and palpitation. The second patient, who was 35 years old, had been married for four years and had given birth to two children; she had had two miscarriages, the last having resulted three months previously.

The PRESIDENT thought that both these cases illustrated very well the fact that myomata caused miscarriage. DR CRIMMON FITZGIBBON said that when he had been preparing statistics of the incidence of fibroids during his Mastership of the Rotunda Hospital he had been surprised by the large number of cases of fibroids in women who had had children. The majority of these patients had been married; they were either women who came at the menopause or were aged about 30, had had no children, and consulted a doctor because of sterility. He thought that the old idea that fibroids were associated with sterility or celibacy was not at all supported by statistics.

AT a meeting of the Section of Laryngology of the Royal Society of Medicine on November 6th PROFESSOR J. ESTEVAN SUEFHAN of New York gave a cinematograph demonstration in colours of plastic operations. Many coloured photographs of the following procedures were shown: (1) operation for relief of unilateral facial paralysis under local anaesthesia through use of sustaining strips of fascia lata; (2) were cicatrix of upper lip and face (lupus) repaired by utilizing a free full thickness skin graft; (3) migration tube pedicle graft from neck for restoration of facial contour (saber defect); (4) the procedure for excision of costal cartilage for use in repairs of the nose and face; (5) the use of the epidermic skin graft for extensive cicatricial contracture of hand. After this demonstration SIR HAROLD GILLIES and MR. IVOR COLLYER showed examples illustrating the end results of similar surgical procedures.

Reviews.

A SYSTEM OF BACTERIOLOGY

VOLUME I of "A System of Bacteriology" the fifth of the series to appear, opens with a chapter on the history of bacteriology. It is rather astonishing to find how ignorant many bacteriologists are of the history of their subject, perhaps in the case of a young and actively growing science like this attention is apt to be focused entirely on the present and the possible developments that the future holds in store. Yet a knowledge of the past is not only of interest but of positive value; what more salutary lesson could there be for the young research worker than the reading of some of the publications of a man like Koch. Professor Bulloch the author of this chapter has a unique knowledge of his subject and knows how to impart it, and the chapter is enriched by a number of illustrations reproduced from some of the early bacteriological classics. Following this is a short account of the morphology of bacteria by R. St. J. Brooks with a very brief note on the investigation of bacteria in the living state by J. E. Barnard. This latter is little more than an indication of the lines along which Barnard is approaching the question, and the possibilities of the method are illustrated by the reproduction of some of his beautiful photomicrographs. Chapter III is devoted to a consideration of the physics of the bacterial cell by E. K. Rideal and Hamilton McCombie—a difficult subject but one of great importance. The growth and reproduction of bacteria, the subject of the next chapter, is dealt with under the three headings of 'Phases in growth,' 'Cell division, colony formation and spore formation,' and 'Life-cycles.' Perhaps in the first section by A. Slator more might have been said on the question of suspended animation because of its bearing on the problem of conservation which is of particular interest in the case of filterable viruses. A. D. Gardner contributes the second section on cell division, colony formation and spore formation, and it is very good though it is somewhat surprising to find no mention of Fildes's recent work when the conditions affecting the germination of spores is under consideration.

Life-cycles in bacteria have had rather a vogue during the last few years, though the majority of bacteriologists adhere to the more orthodox view. H. C. Thornton however gives us some examples such as *B. rubicola* where developmental cycle do seem to pertain, though he recommendably cautions in arguing from such individual findings to bacteria in general. Chapter V on the theory of disinfection by H. Chick is a good account of the subject wherein the lines along which further investigation is required are clearly indicated. This chapter has a section devoted to antiseptic dyes by C. H. Browning who has done so much in this field. The metabolism of bacteria by A. Harden which forms the subject of the next chapter is not valuable, though it will probably prove rather difficult reading for many bacteriologists. Chapter VII on bacterial respiration by J. W. McLeod suffers perhaps from being too condensed, but it is extremely good and offers much food for thought. The short paper on the conception of oxidation-reduction potentials and its application to the problems of bacterial respirations is particularly good.

We always expect something good and eminently readable from Sir Frederick Andrewes, and in his chapter on nomenclature and classification this expectation is fully realized. He never fails to make his subject interesting and to have done this with the subject in question—it is the most readable chapter in the book—is no mean achievement. The volume concludes with an account of variation by J. A. Arkwright who has contributed so much to our knowledge of this question. It is a clear and well planned paper and contains a beautiful plate illustrating smooth and rough colonies of certain organisms.

"A System of Bacteriology in Relation to Medicine." Vol. I. Issued by the Medical Research Council. Vol. I. London: H.M. Stationery Office. 1930. (9½ in. × 6¼ in., pp. 374. Single volumes £1 1s. net; set of nine volumes £8 8s. net.)

THE ENZYME REACTION

A large number of papers by Italian workers on the relation between immunity and protective enzymes have appeared in recent years. This work has now been summarized by Sivori, Rebaudi, and Mennitti in a book on the enzyme reaction.[1] According to these authors, serums of immune animals contain enzymes, differing in character from those of the alimentary canal, which break down foreign proteins. The first products of hydrolysis are insoluble, later intermediate products toxic, and the end-products non-toxic. Theories of skin reactions, anaphylaxis, and the course of infective diseases based on this property are stated in outline.

In the first part of the book, containing only 128 pages, the authors deal also with endocrine disturbances and the etiology of, and immunity to, neoplasms, besides giving the results of certain experiments in detail. The result is neither a thorough discussion nor a brief outline of suggestive ideas, and is wholly unconvincing. In the second part the authors describe their enzyme reaction in detail. It differs from the Abderhalden reaction in that the antigens are liquid, being prepared by hydrolysis to the stage in which the biuret reaction for peptone is strong and the ninhydrin reaction weak, and that the mixture of antigen and serum is not dialysed, but the *ninhydrin*, used to test for products of digestion, is added directly to the mixture. The technique of the application of this reaction to tuberculous and syphilitic serums, and the results obtained by numerous workers are described. The results in tuberculosis appear to be valuable. Applications of the reaction to other diseases are mentioned also.

Although many authors are quoted in the first part of the book no references to them are given. There is no index.

DISEASES OF THE SKIN

Amid the flood of textbooks of dermatology which have appeared within the last few years that by Dr. G. C. Andrews of New York, *Diseases of the Skin*,[2] stands out. It is certainly among the best. While it is of ample size adequately to deal with the subject, the author maintains the proper proportions between what it is important for all students and practitioners to know about the essentials of cutaneous medicine and those quaint and interesting rarities which appeal almost exclusively to the specialist, whose attitude towards them often resembles that of the collector of postage stamps towards unique specimens of the philatelic art. Dr. Andrews has brought his account of the subject thoroughly up to date, and in doing so has taken immense pains. There is no better evidence of this than the vast bibliography appended to each chapter, which shows how thoroughly he and his assistants, whose help he generously acknowledges in the preface, have searched the whole of dermatological literature for all that might be useful in this *magnum opus*.

This is the first general textbook in which any account has appeared of the dietetic treatment of lupus vulgaris, now undergoing so thorough a trial in Germany. Dr. Edgar Mayer, who furnished the author with notes on the subject taken during a personal visit to Germany, has, it is interesting to observe, also tried the diet (the chief features of which are low content of sodium chloride, protein, and carbohydrate, and an enhanced proportion of fats and vitamins) on thirty patients with advanced pulmonary tuberculosis who had proved refractory to all accepted methods of therapy. He states that good results were obtained in about half the cases. Dr. Mayer was very favourably *impressed with the results obtained* from the diet at Munich, Giessen, and also at Leysin. Dr. Andrews has long been interested in the physical methods of dermatological therapy, and among the most useful chapters is that on ultra-violet light. As might be expected, he is conservative in his estimation of the value of ultra-violet rays in general dermatology, and definitely states that they must be considered inferior to *x* rays in all-round utility. There is one field for their action, however, which deserves to be better known than it is, and that is in the treatment of pitted scars, such as are often left after severe acne. In these, blistering exposures to ultra-violet light often lead to marked improvement. Another topic recently much discussed by dermatologists is the thallium treatment of ringworm of the scalp which the reader will find very judiciously dealt with in this volume. The author concludes that its *greatest* opportunity lies in the treatment of severe epidemics of tinea capitis when adequate *x*-ray treatment is not available, and also in combination with *x* rays for the treatment of adults for diseases of the skin requiring epilation. This is a field which has not as yet received much attention. Dr. Andrews has also used radium itself in the treatment of ringworm in very young and restless children, the applicators being fixed by strapping to the scalp.

A special word of commendation must be accorded to the illustrations, which are both numerous and excellent. In the volume of just over 1,000 pages there are nearly a thousand illustrations, for the most part excellently reproduced from clinical photographs, but there are also many diagrams explaining various points of technique, which will be found most useful. The whole volume is excellently got up, and, considering the amount of matter contained in it, remains moderate in size and easy to handle. We commend it with confidence both to general practitioners and to specialists.

PHYSIOLOGY FOR STUDENTS OF MEDICINE

Little need now be said in praise of the excellent treatise on *Physiology and Biochemistry in Modern Medicine*,[3] by Professor J. J. R. Macleod. It has reached its sixth edition in some ten years for the very good reason that it gives one of the best and most readable accounts of physiology particularly of the metabolic phase of physiological activity, in any language. The present edition, except that it records advances that have taken place in the last three years, differs but little from its predecessor. But we adhere to the opinion expressed in our review of the fifth edition that it was a mistake to expand this excellent book so as to make it serve as a textbook of physiology for students of medicine. In the first place the expansion has not been in all respects sufficient for this purpose, some subjects—for example, reproduction—being omitted from Professor Macleod's survey. Secondly, while the book fulfils the needs of those who have already some knowledge of the fundamentals of physiology, it makes very difficult reading for the novice.

A perusal of the text recalls the issue raised by some editorial comment on Sir Arthur Keith's oration on evolution in modern medicine (May 17th, p. 913). "The medical student has much to learn and only a short time in which to learn it, and the practitioner of medicine deals in very practical affairs. Our pastors and masters must realize this position for if, as we are told, physiology in the medical curriculum can now only be covered by three teachers where formerly one sufficed, it is certain that some selection in relation to utilitarian values will have to be made so far at least as the medical student is concerned." Teachers of physiology are not blind to the problem of relating their teaching to utilitarian values. Most of them, we believe, do not forget that physiology is, in the old Scottish phrase, the institutes of medicine, and in a very real sense an introduction to medicine. But what are the limits of the utilitarian? Are a few words on function following a detailed anatomical description enough? Clinically the subject is far too *fundamental and* too living to be dismissed in that way. If, on the other hand, it is allowed to become too copious, too abstract, and too concentrated on matters of purely academic interest, the average medical student will ask himself and his fellows What is the practical value of this material? What, for the lack of a better word, may be called the theoretical physiology must stand, but it should as far as possible be illustrated by clinical applications. Every

[2] *Diseases of the Skin*. By George Clinton Andrews, M.D. Philadelphia and London: W. B. Saunders Company. 1930. (Sup. roy. 8vo, pp. 1091. 983 figures. 35s. net.)

[3] *Physiology and Biochemistry in Modern Medicine*. By J. J. R. Macleod, M.B., LL.D., D.Sc., F.R.S. Assisted by Rex G. Pearce, A. C. Redfield, N. B. Taylor, and J. M. D. Olmsted, and by others. Sixth edition. London: H. Kimpton. 1930. (Roy. 8vo, pp. xxxii + 1074, 295 figures. 42s. net.)

teacher of physiology has appreciated the general increase of interest in his auditors when he connects the physiology he is teaching with some clinical condition Probably the best result would be attained by the use of a short didactic textbook of physiology in which commonly accepted facts of the subject are plainly stated, and a textbook of reasonable dimensions and price which deals with 'clinical" physiology It is a common complaint of clinical tutors that many students of medicine fail to carry forward to their clinical studies either an adequate memory or an adequate appreciation of the data given them in the course of their training in physiology Obviously this may arise because of mental shortcomings on the part of the student, but it may equally readily and with as much justice be ascribed to faults in the teaching of physiology

THE WOUNDED BEHIND THE LINE

Unknown Warriors[1] is a war book It is not concerned with fighting but describes the immediate aftermath of battle—the fate of the wounded in the hospitals behind the line The author, Miss K F Luard, spent four years in France and much of that time was in casualty clearing stations In letters, written at all sorts of odd moments, he gives an intimate description of a nursing sister's life in a hospital near the front line The slack times preparing for the various 'pushes' the rush periods when the staffs were almost overwhelmed with crowds of wounded the lighter moments when the sisters went picnicking in the woods, the minor horrors of war, the mud the blood, the shelling are all depicted by one who, amid the turmoil and stress of war, never lost her interest in her work, her admiration for the bravery, and her sympathy for the suffering that surrounded her These letters were almost certainly not written with any idea of publication and in the absence of such motive they ring with an absolute sincerity which adds greatly to their merit Amid the plethora of literature that is being written, and will still be written about the war, it is inevitable that such a book should appear We are fortunate in having the subject presented by one who avoids all cheap devices to disgust her readers and yet draws an impressive picture of the cruelty and horror of war Two things stand out clearly the stoical courage of the wounded and the endurance and devotion of the nursing sisters Miss Luard treats her subject with a sure and certain touch as long as she keeps within the confines of the hospital When she strays from these well-defined limits and repeats gossip and reports about the military situation, gleaned from various sources we see the truth of General Rawlinson's statement, Rumours generally start in the casualty clearing stations ' The book may be recommended to anyone—doctor or sister—who is interested in the subject of military nursing It will also appeal to a wider public, who will find here a fresh picture of the war, drawn from a different angle

TABULAE BIOLOGICAE '

The sixth volume of *Tabulae Biologicae*[2] consists of about 100 pages of tabulated data relating to zoology, and concludes with nearly 200 pages of index The first four volumes of this work dealt with physiology and biochemistry and the fifth volume with botany The present volume deals chiefly with invertebrate zoology, for the first four volumes contained a large amount of data concerning vertebrate zoology The index however gives references to relevant matter in all six volumes As regards the contents of the volume now under review these are so varied that it is difficult to give a short indication of their character The data comprise the most varied information concerning the biochemistry, physiology distribution, life-cycle and mode of reproduction of the invertebrates The worms are dealt with particularly fully 200 pages The arthropods however are only allotted forty pages, which seems a somewhat inadequate space The most notable features of the vertebrate section are data regarding snake poisons, and a series of tables providing information about the reproduction of a large number of birds and mammals The volume should prove of great value to zoologists, and parasitologists also will find in it much useful information In general we may say that it maintains the high standard set by the previous volumes

NOTES ON BOOKS

Of the articles in the September instalment of *Annals of Medical History*,[3] two deal with the same subject for Dr L J Moorman contributes a paper on tuberculosis and genius as manifested in St Francis of Assisi and Dr R L Pitfield writes at greater length on John Keats the reactions of a genius to tuberculosis and other adversities and graphically describes the tragic mismanagement of his case by various medical advisers among them Robert Bree and Sir James Clark Dr M H Goldstein traces the influence on physiological concepts of Claude Bernard, whose portrait is borne on the cover Bernard in early life wrote a successful vaudeville, *Le Rose du Rhône* and carried another to Paris where however he was fortunately diverted to medicine and became Magendie's official *préparateur* at the Hotel Dieu A syphilitic skull found by Dr J C Tello in an ancient burial place in Peru which other evidence shows to be pre Columbian is described by H C Williams and cannot fail to interest those who differ from Sudhoff's opinion that syphilis was not imported from America Professor A S Warthin continues his well illustrated account of The Physician of the Dance of Death and describes the pre Holbein manuscripts block books, and incunabula Dr J H Lloyd defends Benjamin Rush against his critics remarking that eulogies are now less common, and that it has become fashionable to debunk history Infant welfare in the eighteenth century is considered by Dr F Caulfield and Mr Lambert Rogers of Cardiff sketches the history of craniotomy In the article on William Hunter's obstetrical career Dr G C Peachey adds some knowledge to the store he published in his well known book on the two Hunters Dr R H Major writes on the Ebers papyrus and a catalogue is given by Mr J F Ballard of the 257 incunabula in the Boston Medical Library

Dr W Bolton Tomson of St Leonards-on Sea has compiled a useful summary of the present position in a pamphlet entitled *The Housing Problem in its Relations to the Tuberculous and Tuberculosis Care Committees*[4] He indicates the great importance of providing suitable homes for necessitous tuberculous persons with a view to securing more rapid progress in the campaign against this disease He refers in detail to the views and propositions put forward by various authorities in this country and in France and offers certain specific suggestions for consideration One of his main points is that new houses should be made available for elected tuberculous patients at rents they can afford to pay after the expense of getting to and from their daily work has been taken into account The tenants would be subject to a signed agreement ensuring that everything possible was being done by them to arrest the spread of the disease The extra expenditure entailed by such provision of housing accommodation should Dr Tomson thinks be undertaken by the local tuberculosis scheme, in some instances it might be advisable to form a subcommittee of the tuberculosis care committee to supervise these tenants It is pointed out by the author that such a scheme of allocating houses to tuberculous persons has already been adopted in some parts of this country and also of the Continent and he discusses the possibilities brought into being by the Local Government Act in this connexion

PREPARATIONS AND APPLIANCES

EPINALIN

Epinalin is a combination of adrenaline (1 in 10 000) and ephedrine sulphate (1 in 50) The preparation is intended for application to the pharynx and nose by means of an atomizer It can also be applied to mucous membrane on a swab By these drugs produce vaso-constriction adrenaline produces a rapid but transient action whilst ephedrine produces a prolonged action The mixture thus ensures an immediate effect followed by a sustained action The mixture has been found useful in a large variety of conditions such as rhinitis hay fever and nasal catarrh it can also be used to check bleeding from mucous membranes This preparation is made by Messrs. Burroughs Wellcome and Co

NEW MOTOR LEGISLATION.

BY

STENSON COOKE,

SECRETARY, THE AUTOMOBILE ASSOCIATION

In the early days of motoring, when the utility of the motor vehicle was in the balance, medical men were among the first to realize the comparative advantages of the motor vehicle To-day the motor car is indispensible to the medical profession The few motor cars of those early days were regarded by many as dangerous machines, but since then motoring has made phenomenal strides The thousands have become millions The wonderful development of mechanical transport completely altered the everyday life of the public, and new legislation to meet these changed conditions has been long overdue

Those who motored in the first few years of the present century will have realized that for over twenty-five years the law has been unchanged During that time Royal Commissions and Departmental Committees have been appointed from time to time to investigate the legislative problems of motor transport, but it is only now that the results of those investigations have been given definite effect About a year ago the Road Traffic Bill was introduced in the House of Lords At the beginning of August last that bill received the Royal Assent

Dangerous Driving

The new Road Traffic Act abolishes the twenty-mile speed limit imposed in 1903 The futility of this artificial restriction was apparent from the start, and its only real value was as a means of extracting fines from the pockets of otherwise law-abiding citizens for the technical offence of exceeding the fixed limit There was no question of danger to others, and the twenty-mile limit contributed nothing to the safety of the public

Perhaps I may be pardoned for saying at this point that as far back as 1910–11 the Automobile Association took the initiative in drafting a new Motor Car Bill containing provisions for cancellation of the speed limit Since that time there has been a growing body of opinion in favour of repealing the speed limit and increasing the penalties for dangerous driving The main objection to the fixed limit has always been the fact that, whilst under some conditions it is possible to drive safely at thirty to forty miles per hour, in others a speed of only ten miles per hour might be dangerous

These important factors are recognized in the new Act, but this does not mean that the dangerous or inconsiderate driver will be allowed to imperil others The law in regard to dangerous driving is tightened up considerably, and a new offence of "careless driving" is created Motorists must still drive cautiously and with reasonable consideration for other road users The courts have comprehensive powers to suspend driving licences, and the penalties for dangerous driving have been increased, for the first offence to £50 or up to four months' imprisonment, and for the second and subsequent offence £100 or up to four months' imprisonment, or to both such fine and imprisonment

These increased penalties rendered it necessary, in the interests of the rank and file of motorists, that there should be adequate safeguards against unjust convictions for dangerous driving An amendment was obtained which gives every person charged with this offence the right of electing to be tried by a jury Also, to remedy the present position in which a motorist may be entirely ignorant of the details of the charge he has to meet until he appears in court, the A A was instrumental in securing that where a person is prosecuted for reckless, dangerous, or careless driving he shall not be convicted unless

(*a*) He was warned at the time the offence was committed or
(*b*) the summons was served within fourteen days of the commission of the alleged offence or
(*c*) a notice of the intended prosecution giving details as to the nature time and place of the alleged offence was served on or sent by registered post to the driver or registered owner of the car within fourteen days of the commission of the alleged offence

Drunkenness

The offence of being drunk in charge of a motor vehicle has been extended to cover a person who, when under the influence of *drugs* is incapable of having proper control of the vehicle For the first offence a fine up to £50 imprisonment up to four months, may be inflicted For second or subsequent conviction the maximum penalty increased to £100, or four months' imprisonment to both such fine and imprisonment The courts have also wide powers to disqualify a person from holding licence It will be seen that the penalties for this offence are substantially the same as for dangerous driving

Third Party Risks

Compulsory third party insurance is also a prominent feature of the new Act When it comes into operation January 1st, 1931, a person will not be allowed to use or permit any other person to use, a motor vehicle on the road unless it is covered by insurance against legal liability in respect of the death of, or injury to, any person caused by that vehicle Property is not covered Regulations have yet to be made as to the exact manner in which the will operate, but, in addition to the usual policy the insurance company will hand to the owner a "certificate of insurance," and when applying for his car licence this certificate must be produced

Fitness of Drivers

The question of physical fitness has now been embodied in the law of the land Individual tests of fitness before driving licences were granted was the original proposal but investigations showed that the small benefit to be derived from these individual tests would be out of all proportion to the expense and administrative work entailed in setting up the necessary machinery throughout the country for carrying out such tests As an alternative every applicant for a driving licence will be required to make a declaration as to whether or not he is suffering from any disease or physical disability which would render it dangerous for him to drive

The important question as to what diseases or defects shall constitute a definite bar to the driving of a motor vehicle is still the subject of discussion, but epilepsy and very defective eyesight will doubtless figure in this There is, however, every indication that the regulations in their final form will not be unduly restrictive or irksome

Other Provisions of the Road Traffic Act

The provisions of the Act relating to the prevention of "joy riding" or tampering with cars are of considerable interest to medical men, who are compelled unavoidably to leave their cars on the roadside for various periods No longer will the individual who takes away the car of another be able successfully to advance the plea that he was only "borrowing it" and intended to return it That, in effect, is what has happened in the past The person who drives away a car without the consent of the owner or other lawful authority will be liable to heavy fines and substantial terms of imprisonment Similarly, a person who interferes with the brakes or other part of the car mechanism will be subject to heavy fines

From time to time there has been a good deal of discussion as to the minimum *ages at which* persons should be allowed to drive various types of motor vehicles The Act alters the present minimum age for motor cyclists from 14 to 16 and also restricts the driving of heavy locomotives, light locomotives, motor tractors, and other vehicles other the ordinary motor car class to persons of not less than 21 years of age In each case persons who were driving in the six months prior to January, 1930, are unaffected

These are a few of the important changes contained in the Road Traffic Act There are other new provisions such as (*a*) prohibition of motor racing on a highway (*b*) restrictions as to pillion riding, (*c*) preparation of a Highway Code by the Minister of Transport, (*d*) the limitation of hours of work for the drivers of heavy motor vehicles, (*e*) the appointment of Traffic Commissioners (*f*) the institution of mobile police, etc Space does not permit of detailed reference to all these points but, taking the Act as a whole, there is no doubt that it contains many improvements on the obsolete law of the past twenty-five years, and that, whilst the reasonable motorist need fear no fears as to the effect of the new Act, it is clearly a definite attempt by Parliament to deal severely with the dangerous or drunken driver and provide measures for increasing the safety of the public

British Medical Journal.

SATURDAY NOVEMBER 15TH, 1930

PUBLIC HEALTH AND MATERNITY WELFARE.

THE judicious person interested in public health matters and in social movements related thereto reads each year with great advantage the annual report of the Chief Medical Officer of the Ministry of Health. Most of the subjects dealt with in that volume are of first rate importance, and Sir George Newman's method and style in setting them forth are always extremely attractive. In last week's *Journal* (p. 792) we began our summary of his report for the year 1929,[1] making *special reference to three of its sections*, and a further notice appears this week at page 836. It is to be hoped that these short articles will not satisfy the curiosity of our readers, but that at least the greater part of the report (varying in accordance with varied interests) will be widely studied. For buried within it, as usual, will be found a number of admirable essays full of acute observations and suggestions on matters of real moment to the medical profession and to the public. As illustrations may be mentioned the paragraphs touching the hygiene of pregnancy, contraceptive methods, the efficiency of the health insurance service, the increase in sickness insurance *claims and medical certification*, consultation of medical officers of health with the profession in general, the imperfect notification of tuberculosis, cancer curers, and the education of the public in health matters.

It may be that "buried" is too strong a word to use of these paragraphs; yet it seems certain that some medical officers of health and many members of public health authorities and other interested persons would never be in a position to avail themselves of their suggested wisdom if attention were not specifically drawn to them. At the present time, when very important new health duties have been placed upon county, borough, *councils and county councils*, many of whose new members possess much zeal but little experience, this is of peculiar moment. Intensive agitation by relatively small bodies of persons in favour of this or that medical remedy or surgical procedure or social panacea is liable to have an altogether undue effect in the absence of scientific knowledge and an atmosphere of reason. It is obvious, too, that great importance should be attached to the appointment of new medical officers in the public health service in view of their extended duties and especially to the staffing of the Poor Law hospitals which have been transferred to the new administration.

The appointment of *local medical practitioners* or specialists for outdoor or institutional service, the question of paying wards, the provision of facilities for medical education in institutions, the extension or restriction of the medical services of the Authority—all these are issues in which the medical officer of health should take such counsel as will better qualify him to offer timely and competent advice, and he should do this whether or not there be a local medical advisory committee. In areas in which there are medical schools or university and hospital centres the medical officer should advise his Authority to establish means for close and friendly co-operation. Full advantage should be taken by the Authority of the special skill and experience in medicine and surgery thus available. There should be no lack of willingness on the part of any branch of the medical profession to help local authorities and their officers in such ways.

Another *urgent matter in relation to the state of the* public health is reviewed by Sir George Newman in his chapter on maternity and child welfare. This is peculiarly opportune because the latest returns of maternal deaths are now given, and because the recent reports of Departmental Committees and the maternity schemes of responsible bodies are available for comparison one with another. As regards the statistics these do not reveal any material improvement in the situation generally, but they demonstrate that averages, as is well known, may be fallacious and that all parts of the country are not alike in the dangers of childbirth. In London the maternal death *rate is lower than in any other area*, both for puerperal sepsis and for other causes, and the rate for Wales and for the northern districts of England is notably higher than elsewhere. There are even particular towns, especially some six or seven in Lancashire, which reappear year after year as those with the highest rates. Though there is room for improvement everywhere, no doubt it is safe to say that an intensive campaign in such towns and in Wales would be reflected in a material improvement in the average figures for the whole country. Perhaps this consideration is among those which have influenced the Minister of Health in his recent announcements that the *immediate policy of the Government will be to urge*, and if necessary to enforce, upon local authorities a fuller use of the powers they now possess rather than to attempt to establish at once any more widespread *and comprehensive service*.[2] Economic circumstances probably furnish less justification for the postponement of a national maternity service on the lines proposed by the British Medical Association and the Departmental Committee than for that of any other social service, but no serious objection can be urged against the Minister's policy provided certain conditions are fulfilled. Such conditions are (1) that when any further ante-natal clinics are established and in connexion with any extension of the work of existing clinics the local general practitioners shall be fully utilized for such work, so that practitioners who are liable to be called in at the confinement itself may be those who have knowledge of and responsibility for the patient during pregnancy; (2) that arrangements for specialist consultation and service, whether ante-natal or at the time of the confinement or thereafter, shall be made with part-time consultants; (3) in general that no provisional arrangements shall be made which would interfere with the early establishment of the complete service, and especially that nothing should be done to prevent the linking of maternity work with a national insurance system; and (4) that negotiations shall be at once begun with all those concerned in the establishment of a national maternity service, so that the settlement of the difficult financial and administrative questions involved may be facilitated. Mr. Greenwood has himself announced this first condition as part of his policy, and preparation may now be looked for. Meanwhile there is every reason to proceed with such reforms in the training of midwives and the education of medical students as have been recommended by the Departmental Committee or as may emerge from the consideration now being given to the subject by the General Medical Council.

SPECIFIC AGGLUTININS AND PATERNITY

The presence in the blood of individual specific substances by which one man can be recognized from another, and the possible transmission of such characters from parent to offspring, are a matter of interest alike to the geneticist, to the clinician, to the legal authorities, and to the doubting parent. If such individuality were capable of demonstration many doubtful claims of legitimacy could be definitely settled, and if it could be definitely detected in blood stains, for example, a great advance in criminal investigation would be made. The presence in human blood of specific agglutinins and agglutinable substances, and the knowledge that these are transmitted according to Mendelian principles, has certainly done something towards reaching this ideal. Professor Karl Landsteiner of Vienna, whose name is so closely associated with research on the specific isohaemagglutinins in blood and the distribution of such factors in four main groups, has just been awarded the Nobel prize *in medicine*, and this must be a source of satisfaction to all those who have so keenly followed his work.

Since Landsteiner first observed, in 1900, that the agglutination of the red cells of one individual by the serum of another was by no means a chance process, but that it followed definite relationships, a considerable literature concerning blood groups has grown up, scattered over a wide range of journals. The publication of a handbook focusing the work on this interesting subject is opportune, and, in his *Blood Grouping in Relation to Clinical and Legal Medicine*,[1] Dr. Laurence Snyder has brought together the salient facts and hypotheses. His book deals with the indications for and against transfusion, the choice of a donor, and the various methods, direct and indirect, used in the transfusion of blood. Some attention is paid to the technique of blood grouping, but this is rather sketchy, as is the technique for identifying the group in blood stains for medico-legal purposes. These parts of the book occupy in all about thirty pages. More interesting are the chapters on the hereditary transmission of the group characters. Snyder discusses in a simple manner the Mendelian hypothesis of heredity, and applies this to the transmission of factors associated with the red corpuscles to form the four blood groups in man. Von Dungern and Hirszfeld's original hypothesis that these were inherited as two independent pairs of Mendelian factors (the agglutinogens A and B being dominant to their respective agglutinins *a* and *b*) is discussed, together with the more recent views of workers in this field. The hypothesis of triple allelomorphs put forward first by Bernstein from statistical observations, and confirmed by Snyder and others on observed hereditary data, is dealt with at some length. According to this the genetic factors responsible for the four groups are all located on the same spot on a single pair of chromosomes. Three factors are supposed, two of which (A and B) are dominants, and one (O) recessive. From the point of view of inheritance the hypothesis of triple allelomorphs does not question the validity of the original hypothesis, the only difference being in unions in which one of the parents is in group AB, *in which the possible blood groups in the offspring are more restricted*.

There seems to be no doubt that isohaemagglutinogens never appear in a child unless they were present in one of the parents, and when neither parent has an agglutinogen none of the children can have it. The group test therefore offers a means of deciding certain questions of paternal identity. Snyder discusses in some detail the medico-legal value of the group test and also its limitations with reference to alleged paternity. Reference is made to the fact that no one of the various hypotheses of heredity has been satisfactorily proved, and also to the fact that even the division into four groups only is open to certain objections. Landsteiner and Levine's work, showing that there are a number of more or less definite agglutinable factors within the four major groups, is mentioned in this regard. Todd's work on cellular individuality is too recent for inclusion, but this work suggests that the red cells of any one animal have distinctive characters by which they can be clearly differentiated from the cells of any other animal of the same species by comparatively simple serological methods. Todd has shown also that such specificity is transmitted by one or both parents to the offspring. Thus, if a polyvalent serum, prepared by using the blood of a large number of hens as antigen, is exhausted with the blood of both father and mother, it will not agglutinate the blood of the chickens of these two birds. This work is not applicable to human beings at present, but it points to an almost infinite range of specificity within species. These specific bodies differ apparently from the specific bodies which are associated with the four recognizable blood groups.

In passing, we might mention Zangemeister's work on the optical properties of the blood of parent and offspring. This research suggests that when the blood of closely related persons is mixed, the luminosity, when viewed through the ultra microscope, tends to diminish, due to agglutination of the protoplasmic colloids. Zangemeister's work is in the experimental stage, but it is of the greatest interest, not only in connexion with proof of paternity, but as another proof of the individuality of the proteins which go to make up protoplasm.

DR. CHEVALIER JACKSON

The name of Chevalier Jackson has long been familiar not only to every specialist in laryngology, but also to every English-speaking practitioner of modern methods *in medicine*. His recent visit to London, therefore, is an event of unusual interest. As Mr. Frank Rose, president of the Section of Laryngology of the Royal Society of Medicine, said in welcoming Dr. Jackson at the dinner given to him last week, a large number of those to whom his name, his writings, and his instruments are well known, but who have never been able to visit Philadelphia, have now had the opportunity of meeting him face to face, and of hearing him speak on several occasions, an experience that will leave an indelible impression. The president speculated on which of their guest's achievements would secure for him immortality: his skill in operating on cancer of the larynx, his dexterity in extracting foreign bodies or his bronchoscope. Dr. Jackson's value to his own generation is of a rather different order.

It is no more than a few decades since the laryngologist was a person who did little more than inspect the vocal cords with a mirror. Laryngology dates naturally from the invention of the laryngoscope by Manuel Garcia in 1855. Development since then has been rapid and steady, and in this no one on either side of the Atlantic has played a more active part than Chevalier Jackson. He is still advancing the frontiers of laryngology. The invitation from the Medical Society of London to open a discussion on malignant disease in the chest is a remarkable and gratifying [illegible] The Royal Society of Medicine

too has acknowledged the services of Dr Jackson to general medicine as well as to laryngology by inviting him to address the whole society This is the highest compliment it can pay to anyone who is not one of its own members—an honour jealously guarded and reserved for very few The Barnes Hall has never held a larger or a more appreciative audience than that which listened to Dr Jackson's address on the pathology and treatment of suppurative diseases of the lungs, reported in our issue of October 25th

The welcome that has been extended to Dr Chevalier Jackson sprang from a profound admiration for his personality and his work His modesty and his generous acknowledgement of the help received from his associates and assistants are traits particularly gratifying to his British admirers To Mr Herbert Tilley thanks are due for persuading this distinguished guest to accept the hospitality of London, and we trust it will not be long before he repeats the visit

AMPUTATIONS

By the time the great war came to its official end British limb-fitting surgeons had generally agreed on what their experience led them to think were the principles upon which amputations should be performed and what were the most suitable sites, having regard to the subsequent fitting of useful prostheses The discussion held in the Section of Surgery of the Royal Society of Medicine on April 2nd, on which we commented at some length in our issue of April 12th, and the discussion held on November 4th in the Orthopaedic Section (reported this week at page 823), show that the last nine years' experience has not caused surgeons to change their views except in regard to very few procedures Mr Verrall summed up the developments of amputation practice in the last ten years as follows "an alteration in opinion as to the length of the thigh stump the value of the Syme and of the Stokes-Gritti, the question of drainage in amputations, of treatment of the nerves a consideration of the choice in the case of mid-tibial amputation between an anterior and a posterior flap based on the trophic condition of the leg, and finally the admission of the operation of arthroplasty as a reasonable and eminently successful proceeding for the treatment of stiff joints in amputation stumps" It may therefore be assumed that the theory and practice of amputation has become, for the time at least, stabilized and the paper read by the president of the Orthopaedic Section, Mr P Jenner Verrall, should become a permanent guide to those surgeons all over the country who are liable to be called upon at any moment to amputate a limb The fearful tax laid on life and limb by motor vehicles, which produce as many casualties in a year as a quite respectable military campaign, has vastly increased the annual number of such operations We suggested in our leading article in April that the unfavourable opinion formed of the late results of certain typical operations was perhaps due to the experience having been drawn from war cases in which the condition of the tissues was unfavourable It appears, however, from Mr Verrall's paper that this is not the case, for unfavourable late results of Syme's amputations and of those with long thigh stumps have been met with in civilian practice In the case of Syme's amputation the recent experience of orthopaedic surgeons appears to be in conflict with that of the limb-makers most of whom can put on record cases which after many years, are still satisfactory One well known firm wrote on this subject as follows

> We have quite a number of customers who have been wearing artificial feet for Syme's amputation for ten years or more some for twenty thirty and even forty years and although from the aesthetic point of view we do not like the amputation as it is very difficult to conceal the fact that a limb has been lost especially in the case of a lady we are bound to state that considered as an amputation only it is an entirely successful one.

Can it be that some change in the procedure of late years has unfavourably affected the durability of good primary results? It is admitted by its critics that Syme's amputation gives in some cases excellent and lasting results Is there no way of telling in advance the durable from the transient good stump? The question is important to the patient, for there is no comparison in comfort and in economy between the Syme prosthesis which leaves the knee free, and that for a mid leg amputation, with its cumbrous knee joint and tight-fitting laced thigh corset involving as it does the necessity for very skilled and accurate fitting of the socket below the knee

PREVENTION OF PSYCHOLOGICAL DISORDERS

ALTHOUGH psychologists are tending more and more to the view that psychological disturbances in the adult are derived from faulty environment in childhood or infancy, the avoidance of such disturbance is seldom regarded as a serious part of preventive medicine Dr R D Gillespie, in his paper (printed at page 807) on the psychology and psychopathology of childhood puts this aspect of the work of the psychologist in a clear light In dealing with children the psychologist has the advantage of handling young material, plastic and gifted with marked powers of recuperation A child is not merely remarkable for the suddenness with which he is prostrated by disease but for the vigour with which convalescence progresses, and in his mental reactions he shows a similar buoyancy Usually, Dr Gillespie finds, psychological symptoms in the child depend on the frustration or misdirection of some of his tendencies by his environment, and an adjustment of the offending environmental factors causes the symptoms to disappear No analysis of the child's mental state is usually necessary and the adjustment can be made through interviews with parents as soon as the fundamental problem has been solved There is a danger, against which he offers a warning of interpreting the child's mental state in the terms of adult experience such an attitude must inevitably bias the judgement and lead to errors In the child the prognosis for psychological disturbance properly treated is nearly twice as good as in the adult according to a small group of statistics obtained by Dr Gillespie at Guy's Hospital, in this group only about a third of the adult patients could be classed as improved or cured while the number of children who recovered reached 65 per cent There is a possibility that a proportion of these children might have recovered without the aid of the clinic so strong is the urge to adaptation but it is equally probable that a certain number of those who found adjustment difficult in childhood would have progressed to a more serious disability in later life if they had been suffered to go untreated It is on these grounds that Dr Gillespie urges the importance of establishing a sound adjustment in childhood believing that herein lies the prevention of adult neurotic and perhaps psychotic disorders He points out that certain morbific traits appear in childhood at a time when characteristics of a similar type are modifiable, though it has yet to be decided whether the morbific and modifiable characteristics are the same There is an opinion however among certain of those psychologists who have worked with children that the development of adult psychoses is being prevented at least in some cases If this is really so its importance can scarcely be over-emphasized On economic grounds alone the cost to the community of mental hospitals is considerable while the neuroses are responsible for a heavy toll in loss of work every year At present our knowledge of psychological disorders in childhood is handicapped by lack of data other than the retrospective statements of adults.

[1] *British Medical Journal* 1930 i 693.

Dr Gillespie believes that the psychologically minded paediatrician is the person best fitted to carry out research among children, by observation of the onset of these disorders The psychiatrist, who at present sees only the end-results, would thus be enabled to obtain his material in the early stages, by reference from the paediatrician, and symptoms due to maladjustment would be open to treatment before they had acquired any pronounced hold on the character of the child

THE MUSCLES OF THE LARNYX

The annual Semon Lecture, under the auspices of the University of London, was delivered at the House of the Royal Society of Medicine, on November 6th, by Mr V F Negus The lecturer devoted himself to showing, with the aid of demonstrations in comparative anatomy and physiology, how well proved was the theory put forward by Sir Felix Semon with regard to the muscles of the larynx This organ, said the lecturer, might be described as a scaffolding of cartilages and two sets of muscles, which he called respectively the sphincteric and the dilator Semon, in his *Clinical Remarks*, published in 1881, laid it down that if there was any interference with the common nerve supply to the two groups of muscles, the dilator muscles were paralysed sooner than the sphincteric In remarking upon this far-reaching law, the lecturer traced the evolution of the larynx from its primitive forms to its complicated structures in man Semon himself started by regarding the larynx as the organ of voice, but from a study of comparative anatomy it was evident that a very large number of animals never used it for this purpose, vocalization was only a secondary function of the larynx From a study of lunged fish, such as the Amazon mud-fish, it appeared that the primary function of the sphincteric muscles of the larynx was the protection of the respiratory epithelium If this muscle did not act, certain fishes would be drowned as soon as they went under water, but the sphincteric muscle was able to close the larynx like a purse-string The lecturer considered this to be an important factor in explaining Semon's theory that the sphincteric muscle of the larynx originally came into being before the dilator muscle, and had a vital valvular function in protecting the lungs It was the general rule, seen in other parts of the body, that an organ of vital importance and earlier origin survived an organ of less vital importance and later origin Various changes and adaptations had taken place in the sphincteric muscle in the course of evolution Thus some creatures, such as crocodiles, were enabled to keep their mouths open under water and catch prey, so long as their snouts were above the surface In some animals the protective closure was supplemented by closure of the nostrils, and there were curious modifications of the larynx in ruminating animals Turning to the dilator muscles, Mr Negus said that these did not belong to the larynx in the simpler species later, they became included, and in man assumed a much more important position Here again he showed examples of the larynx in various animals, including the tilted larynx in the muntjac or American barking deer In man the dilator muscles had assumed a greater importance They had to contract to hold the glottis open, otherwise the membranous folds would stick together and air could not enter Nevertheless, the greater importance of the sphincteric muscles, derived from their earlier origin, remained, and Semon's law still held good There were certain secondary functions of both groups of muscles The sphincteric muscle, for example, had a function of its own in retaining air in the lungs, and the dilator muscle the function of contraction during simultaneous respiration and deglutition, a mechanism brought to perfection in whales and porpoises, where the dilator muscles had a part to play in the highly specialized modification of the blow-hole on the top of the head Phonation was one function of the combined sphincteric and dilator muscles, but it was a function acquired late The larynx happened to be a convenient organ of voice, but it was not evolved for that purpose, its primary object being the protection of the air tract Semon thought that the movement of the glottis might be looked upon as part of respiration Actually it was the first act in respiration, the glottis opening at the beginning of inspiration, before the respiratory muscle contracted, also it started to close before expiration had ended After anastomosis of the phrenic nerve, it was interesting to note that the timing had changed, the movement of the vocal cord taking place at the same time as contraction of the diaphragm Sir David Ferrier once suggested that the muscles of the larynx might be compared with the muscles of the limb, in which the extensor muscle were paralysed before the flexor, should there be any injury to the nerve supply, that was probably a protective mechanism In an arboreal species it was obviously most important for an animal to retain the power of hanging on to a branch But the same question of relative importance was involved in the larynx, and in every respect comparative anatomy supported Semon's theory At the close of the lecture Mr Negus was presented with the Semon medal by Lady Semon

DRAFT POTTERY REGULATIONS

In our issue of March 23rd, 1929 (p 562), we called attention to the reports on the incidence of silicosis in various industries—the pottery industry, the sandstone industry, and others The Home Office wisely approaches the considerable problems arising out of the evidence so obtained in two ways first, by schemes entitling those who are found to be suffering from silicosis (or the dependants of those who have died) to obtain compensation, and, secondly, and as far as possible contemporaneously, by the issue of Regulations to minimize the amount of siliceous dust evolved in the processes So far as the pottery industry is concerned, the evidence made it clear that periodic examination by a medical board was desirable As the constitution of such a board is now in sight, since the passage of the Workmen's Compensation (Silicosis and Asbestosis) Act of last session, the Home Secretary has issued draft Regulations (additional to the existing Pottery Regulations) in regard to dust prevention He emphasizes their urgency by stating that, since the Various Industries (Silicosis) Scheme came into force (as recently as in February, 1929) 113 cases of total disablement, including 54 deaths, have been reported Twelve processes (mainly those in which the dust from ground flint is in question) are specifically named which must be carried out under an efficient exhaust draught Everything turns on what is meant by "efficiency" in this connexion We regret to see that no attempt is made at a definition Can it not be determined by an instrument—an anemometer, or the height to which a column of water in a U tube is drawn up—or by a permissible limit of milligrams of dust per cubic metre of air at breathing level (as in South Africa[1]), or by the number of particles under 10 microns as tested by the Owens dust counter (as in Sydney sandstone mining)? Is it still to be regarded as efficient if the back of the hand is chilled, or if a handkerchief is drawn inwards by the draught at the exhaust opening? This is the most practical urgent point in the matter of silicosis—attainment and enforcement of some standard More would be accomplished in the prevention of silicosis by the determination of the dose of particles of free silica under 10 microns which, inhaled daily, would in the course of ten years produce disabling silicosis, than by all the elaborate

[1] Contributions to the Study of Miners' Phthisis By A Mavrogordato South African Institute for Medical Research 1926 p 61
[2] Extract from the Report of the Director General of Public Health New South Wales, for the year 1927

dissertations now being published on its prevalence throughout the world It is impossible not to extend sympathy to employers and workpeople alike over the risks attendant on so useful and, in its output, so beautiful an art and craft The industry has, in magnificent manner overcome the risk from lead poisoning which was another of its banes in bygone years In 1898, for example, from pottery works alone 457 cases of saturnism were reported, last year the number was 14 This success should inspire all concerned to cope with the trouble now brought to light

REGISTER OF BIO PHYSICAL ASSISTANTS

THE Representative Body of the British Medical Association in July, 1928 pointed out the need for the registration of competent and suitable lay persons to whom doctors could with confidence send their patients for electrical treatment and actinotherapy In the following December the Science Committee presented to the Council a report on the practical steps to be taken to organize courses of training in these procedures, and to prepare a roll of persons who had satisfactorily followed such courses A small committee of experts was then formed to draft general lines of procedure, and an arrangement was entered into with the Society of Apothecaries of London to institute a register of approved persons under the conditions prescribed Regulations were drawn up and the first *Register of Bio-Physical Assistants* was printed and published a few months ago under the direction of the Society of Apothecaries[1] This contained full details of what is required in order to become a registered bio-physical assistant a statement of the undertakings which registered persons are required to sign, and the first list of names arranged both alphabetically and topographically At the suggestion of the Science Committee, and with the co-operation of the Society of Apothecaries, we publish in the *Supplement* this week, for the convenience of medical practitioners at home and abroad the topographical part of the *Register of Bio-Physical Assistants* revised to October 31st, 1930 Those whose names appear therein have been approved as persons "competent to dispense the direct current, ionization, faradic currents, sinusoidal currents diathermy, high frequency currents, light and heat, and ultra violet light"

PUBLIC HEALTH CONGRESS IN LONDON

A CONGRESS and exhibition are held every November at the Agricultural Hall, Islington organized by a council composed of representatives of the Ministry of Health the Board of Education, the Board of Control, and the various associations of municipal corporations, county councils, and other public bodies The congress is devoted in alternate years to local administration on the engineering and public works side and to local administration on the side of public health This year it is the turn of public health and the congress, which is to be opened by Mr Arthur Greenwood, the Minister of Health on November 17th and to continue until November 21st has a very full and interesting programme Among those who are giving addresses are Sir Arthur Newsholme, who is to speak on medicine and the State, Dr W M Ash on the school medical service, Profes or E Mellanby on maternal mortality Dr T Beaton, on the mental health problem Dr E S Litteljohn, on mental deficiency and Professor C S Myers, on industrial psychology The chairmen at the various sessions include Sir Herbert Samuel, Sir Charles Trevelyan, President of the Board of Education, Miss Susan Lawrence, Sir Arthur Robinson and Mr L G Brock A special discussion is to take place on the morning of November 21st on the sterilization of the unfit, and among the announced speakers are Dr W F Menzies, Dr A F Tredgold, Dr C P Blacker, and the Right Rev Monsignor Newsome In addition to the ordinary sessions, meetings of various associations are to be held in connexion with the congress The British Hospitals Association is to discuss hospital contributory schemes, the Association of Hospital Officers is to take up the subject of co-operation between the voluntary and council hospitals, and other bodies are to debate sewage disposal, water supply and public cleansing problems Evidently a full week's work is anticipated, and delegates are expected from very many of the local authorities in Great Britain An exhibition filling the vast space of the Agricultural Hall and including plant machinery, and materials used in the various public health services, will be held during the week

[1] *British Medical Journal* May 31st 1930 p 1012

TABULAE BIOLOGICAE

THE six volumes of collected data published in Berlin under the title *Tabulae Biologicae* deserve the attention of workers in biological sciences The appearance of the first volume of the series in 1925 was welcomed warmly in these columns, for the difficulty of hunting down data is well known to all investigators Collected tables of data have long been recognized as an elementary necessity by chemists and physicists, and the lack of anything in biology that corresponded to the volumes of Landolt-Bornstein or Kaye and Laby was a very serious hindrance to research *Tabulae Biologicae* evidently met a widely felt need, for the work, which was originally planned to comprise four volumes dealing with physiological and biochemical data has since been expanded by the addition of botanical and zoological volumes The collection of biological data, even on a modest scale, is a remarkably difficult and tedious task, and it is impossible to escape a feeling of amazement when glancing through the thousands of pages of tabulated data brought together in these volumes Biological workers certainly have reason to be grateful to the authors who have completed this labour, and it is pleasing to learn that the volumes have met with widespread appreciation The editors announce that the series will be continued in periodical form, one volume in four parts will appear annually The bulk of scientific literature becomes every year more overwhelming but we can welcome this particular addition without hesitation because it will serve to reduce rather than increase labour

SIR FREDERICK GOWLAND HOPKINS D Sc F R C P Professor of Biochemistry in the University of Cambridge has been recommended by the President and Council of the Royal Society for election to the presidency of the Society at the anniversary meeting to be held on December 1st

SIR ARTHUR KEITH M D F R S was on November 8th elected Rector of the University of Aberdeen in succession to the late Earl of Birkenhead

AT the Yeomanry Dinner to be given by the Master Wardens and Court of Assistants of the Society of Apothecaries of London on Tuesday next November 18th the honorary freedom of the Society will be conferred upon Mr Arthur Greenwood Minister of Health and the gold medal will be presented to M Fourneau

ORGANIC GASTRIC SYPHILIS

CORRECTION

WE have to correct an unaccountable blunder which occurred in our last issue dated November 8th 1930 Dr David Smith the author of the article on Organic gastric syphilis printed at page 773 was described in the heading as Assistant Physician Royal Infirmary, *Edinburgh* This, of course, should be Royal Infirmary, *Glasgow*

DINNER TO DR. CHEVALIER JACKSON.

The President and Council of the Section of Laryngology of the Royal Society of Medicine held a dinner at the Langham Hotel, London, on November 7th, in honour of Dr Chevalier Jackson, professor of bronchoscopy and oesophagoscopy, Jefferson Medical College and University of Pennsylvania Graduate School of Medicine The chair was taken by Mr Frank A Rose, president of the Section, and the large company included members of the Section from all parts of Great Britain, many of whom had had the opportunity of welcoming Dr Chevalier Jackson on the previous evening at an informal reception given by Sir StClair Thomson

The President, in proposing the health of the guest, began by contrasting his own first experience of seeing an oesophagoscope used in 1899 with his experience at the Jackson Clinic in Philadelphia twenty years later, when he saw Dr Chevalier Jackson remove a foreign body from the bronchus in about two minutes Mr Rose suggested that the man they delighted to honour that evening would perhaps be remembered by future generations not so much for his success in operating on the larynx for carcinoma nor for his dexterity in removing foreign bodies, but would rather be compared to Elias Howe, who invented the sewing machine Howe showed the world that the eye of a needle ought to be at its point, similarly Chevalier Jackson would perhaps be remembered longest as the man who taught the world to place the light of a bronchoscope at its tip It might be that when the memory of his other achievements had grown dim, as they merged into the ever-growing stream of medical knowledge, Chevalier Jackson would for all time be known by his bronchoscope

Mr Herbert Tilley, in seconding the toast, said that it "worship of a hero is transcendant admiration of a great man," then, and without flattery, he could assure Dr Chevalier Jackson that he was surrounded by a great company of devout worshippers It might be no compliment to speak of Dr Jackson's great work, *Bronchoscopy and Oesophagoscopy*, as a classic, because that had been defined as "a book which everyone praises but no one reads," whereas this volume was such a source of light and inspiration that it might well be termed the bronchoscopist's bible Mr Tilley then referred to the brilliant exposition of the subject which Dr Chevalier Jackson had recently given before the Royal Society of Medicine, where his audience enjoyed a vivid and artistic description of his methods for dealing with suppurative lesions of the lungs How much he was appreciated in his own city was shown four years ago when Philadelphia awarded him the Bok Memorial Prize Furthermore, he had already anticipated a monument to his name by building a wonderful museum of pathological lesions and of foreign bodies removed by him from the lungs or oesophagus Mr Tilley said, in conclusion, that the sentiments he wished to express on behalf of his colleagues would be most fitly rendered by a modified verse of the poet-physician of Philadelphia, Wm Mitchell

> 'And now you've found with us a second home,
> And in the practice of Life's happiest arts
> You little guess how readily you've won
> The added friendship of our open hearts"

Dr Chevalier Jackson responded to the toast in a speech of characteristic modesty He began by referring with a touch of sadness to his father, who was born in Hull about a hundred years ago, and, after sailing to the United States never returned to England He felt that this splendid welcome would have delighted his father were he still alive It had been suggested, Dr Jackson said, that he might speak on "the making of a bronchoscopist," but a bronchoscopist was born, not made, and in illustration of this he told, with dry and sparkling humour, two stories against himself

The health of the other guests was proposed by Dr Dan McKenzie, and responded to by Dr T Watts Eden, President of the Royal Society of Medicine, and Sir Humphry Rolleston, Regius Professor of Physic at Cambridge

THE STATE OF THE PUBLIC HEALTH.

SIR GEORGE NEWMAN'S REPORT FOR 1929

[Second Notice *]

The average age of the population of England and Wales is steadily rising, owing to a decrease in the proportion of children to the total population, and an increase in the proportion of persons past the prime of life In 1928 the birth rate exceeded the death rate by 5 per thousand living, which meant a net increase of 5 for every thousand of the population This figure was less than half that which obtained during the quinquennium 1921–25, and very little more than one-third of the figure for 1916–20 In 1929 there was a further decrease in the birth rate (from 16·7 per thousand to 16·3), and a substantial increase in the death rate (from 11·7 to 13·4), so that the net increase of the population was further reduced from 5 to just below 3 per thousand living The number of births (643,673) is the lowest, and the number of deaths (532,492) the highest recorded for a great many years The mortality of infants during the first year of life rose to 74 per thousand births, as against 65 the previous year, so that of the reduced number of children born still fewer survived infancy

Causes of Death

The principal certified causes of death were the following

	Per 1 000 deaths.
Diseases of the heart and circulation	225
Bronchitis, pneumonia, and other respiratory diseases	157
Cancer, malignant disease	107
Diseases of the nervous system	82
All forms of tuberculosis	71
Influenza	55
Diarrhœa, enteritis, and other diseases of the digestive system	52
Non venereal diseases of the genito-urinary system	43
Violence	41
Old age	40
Premature birth and diseases of early infancy	31
Measles, whooping-cough, and diphtheria	21
Other causes	69

The deaths from influenza, which numbered 7 754 in 1928, rose, in consequence of the spring outbreak, to 29,084 in 1929 Owing to the complications following influenza, the death rate from pulmonary tuberculosis and from respiratory diseases also increased

Epidemic Diseases

Small-pox showed an increased prevalence in 1929 in and near London, accompanied by a decline in most other parts of the country Generally the disease was of the mild variety The notifications of enteric fever (including paratyphoid) were considerably fewer in 1929 than in the two previous years Scarlet fever continued to be of the mild type, and measles, though once again the most fatal infectious disease of childhood, showed a smaller number of deaths Several local authorities, particularly in London, are using the serum of convalescents to protect selected children who are found to have been exposed to measles infection In infectious diseases hospitals of the London County Council convalescent serum is also being used to check the spread of infection in the wards There were no extensive outbreaks of diphtheria during 1929 with the exception of one of 237 cases with 12 deaths at Poole The investigation of psittacosis is described in the report, the hypothesis of a filterable virus as the causal agent is regarded as the most probable, and certain observers are engaged, with the assistance of the Ministry, in the arduous and prolonged researches necessary to establish it It is hoped shortly to publish a special report on the subject The decline in the notifications of encephalitis lethargica continues, the notifications were little more than one-fifth of the number in 1924 There was a sh[ort]

* The first notice of the Annual Report of the Chief Medical Officer of the Ministry of Health for the year 1929 appeared in the Journal of November 8th (p 792)

rise in the number of notifications of poliomyelitis and polioencephalitis, though the death rate was lower Cerebro-spinal fever continued the upward tendency remarked since 1923

Rheumatism Tuberculosis Venereal Disease

After quoting from recent writings on acute rheumatic infection in childhood Sir George Newman expresses the opinion that no sufficient case has been made out for the routine removal of apparently healthy tonsils in the rheumatic or potentially rheumatic child simply as a measure of prophylaxis against acute rheumatism The removal should only be undertaken if there is some definite local condition, such as obvious enlargement or disease, associated adenitis, or ill health caused by the obstructive size of the tonsils In discussing chronic rheumatism he mentions that the incidence continues to judge from industrial statistics, at about the same level The figures from the approved societies show that rheumatic diseases account for about 14 per cent of total sickness and disablement

The new cases of tuberculosis coming to the knowledge of the health officers of local authorities have shown, especially in the pulmonary form, a steady decline for many years The number of deaths from pulmonary tuberculosis rose slightly in 1929, but was below the figure for 1927 The figures for each year since 1847 show a remarkable consistency of diminution The following table indicates the death rate for tuberculosis of the respiratory system per million living, the figures being taken at intervals of ten years

1847	3 189	1897	..	1,356
1857	2 690	1907	..	1,125
1867	2,653	1917		1 085
1877	2,184	1927	..	744
1887	1 685	1929		738

Several pages of the report are devoted to a discussion of the place of the village settlement in a tuberculosis scheme Sir George Newman regards the village settlement as a highly important experiment in connexion with the problem of after-care

The number of treatment centres for venereal disease at the end of last year was 178 in England and 10 in Wales The cases of syphilis dealt with at the centres showed a decline in numbers, but the number of cases of gonorrhoea was higher than it has ever been It is deduced, however that the figure for gonorrhoea indicates not a real increase, but the greater use of the centres by persons suffering from that disease The low ratio of gonorrhoea to syphilis in females (1 18 to 1) as compared with males (2 76 to 1) suggests the probability that a large proportion of women with gonorrhoea remain untreated

The Cancer Problem

The recorded deaths from cancer per million of population again showed a rise in 1929 the figure being 1 437 as compared with 1,425 in 1928 The rate is higher than in any previous year, and is, roughly double that which obtained thirty-five or forty years ago In males to judge from the death certificates, the most frequent site is the stomach, in females the breast There is a declining incidence among males of cancer of the tongue and jaw and in view of the possibility that a proportion of cancers of the tongue originated in old syphilitic lesions it would be reasonable to attribute this improvement to the higher curability of syphilis The mortality from cancer of the uterus has been falling for some years past, possibly owing to improvements in the care of women during and after childbirth whereby local effects on the cervix which are the precursor of cervical cancer have been diminished From a study of the sex incidence, it would appear that whereas in 1851–55 the susceptibility of females to cancer was more than double that of males in 1921–25 the susceptibility of the sexes was approximately equal From certain other facts set out in the Registrar-General's report Sir George Newman draws the general conclusion that previous local disease or injury is a more important factor in the causation of cancer than susceptibility the resistance varies with the organ concerned, remaining steady in some sites increasing or decreasing in others varying with the sexes and probably also with age Sir George Newman points out that under the powers conferred upon local authorities by the Local Government Act many of these bodies will be called upon to provide treatment for the sick poor of their districts As the sick poor include a large proportion of cancer cases an opportunity of education in preventive treatment will be afforded

"Cancer Cures"

With regard to non professional amateur or quack remedies for cancer, to which public notice has lately been drawn, Sir George Newman states the condition which must be met before it can be stated that one method is superior to another the number of cases must be large enough to avoid errors due to chance there must be no reasonable doubt that the cases were cancerous and the proportion of three-year or five-year cures must be definitely greater after one method than after the other Unless these conditions are fully satisfied no new method of treatment is likely to meet with the general acceptance of the medical profession In matters of this sort the members of the profession are their own severest critics and the scepticism with which they receive accounts of vaunted "cures" for cancer should be attributed to their conviction that such "cures" must pass tests similar to those which experience has shown to be essential Another necessary step in testing the value of a new method is that such an account of it must be given to the world as will permit of claims made on its behalf being confirmed or controverted Experience has shown Sir George Newman says drily, that the reaction of the professed "cancer curer" to such a condition is a certain reserve, he is not too anxious, as a rule to obtrude himself or to submit his methods to the scrutiny of an investigatory committee The main feature of his trade is that his remedy is a secret one, known only to himself It is not contended that the "cancer curer" never treats the cancerous condition nor that he never cures some diseased conditions, it is also possible that he cures some superficial cancers if he uses caustic applications But the medical profession knows that removal can be effected more quickly by some surgical method also with less disfigurement, and usually with less pain

> One may believe that the cancer curer is merely ignorant it seems probable that he is more often a charlatan trading on the facts that some cancers are difficult to diagnose that the preparations he uses sometimes lead to healing of the local disease and that on the part of the public fear of the disease ignorance of the true state of affairs and the secrecy with which the treatment is enshrouded all combine to make them ready victims One may rest assured that if and when some form of treatment for cancer is found which gives result superior to those being obtained by members of the medical profession it will be quite unnecessary to take special steps to give it the prominence it will deserve its virtues will ensure its full recognition

Nothing could be further from the truth than that any professional jealousy enters into the matter or any unwillingness to consider suggestions emanating from outside the bounds of the medical profession

Sir George Newman concludes his remarks on cancer with a reference to the place of radiotherapy While it cannot be said that efforts during the past year to improve the nation's resources in respect of radium treatment of cancer have been untruitful two important points should not be allowed to escape notice (1) the need for fostering a parallel development of x ray therapy with radium therapy and (2) the practicability of pooling resources for radiotherapy in those hospitals which have such small amounts of radium as to lead to inadequate or costly use

Public Health Activities and Special Investigations

A large section of the report is devoted to food and nutrition In the elucidation of the problem of nutrition progress continues to be recorded, but as fresh knowledge

accumulates the complexity of the subject becomes increasingly manifest Some suggestive work by Professor Mellanby gives ground for believing that vitamin A may have an important function in the prevention of infection, and steps are now being taken to test that hypothesis on a large scale

A few sporadic outbreaks of food poisoning occurred during the year, but all were of the usual type The "toxin" type of food poisoning associated with canned or cooked food in which no living bacteria are to be found is no longer of common occurrence Only three outbreaks could be reasonably ascribed to this form of food, in all three, canned veal from one particular foreign factory was suspected Only one outbreak was observed as due to ice-cream An interesting outbreak, due to milk, occurred in an elementary school, the milk was certainly highly contaminated with bacteria of the *B coli* group, but no pathogenic bacillus was isolated

Sir George Newman describes the many activities of the intelligence division of the Ministry, the work of the Ministry's pathological laboratory, the work carried out by medical officers of the Ministry under the Therapeutic Substances Act, and special and auxiliary investigations on port sanitation and other matters In international health he shows that British research and experience have made useful contributions During the past year one of the Ministry's highly placed officers has been sent to Australia to advise on the establishment of a maternity and child welfare division in the Commonwealth Department of Health, and another to the Governments of Kenya and Uganda to advise as to measures to be taken to combat malaria

The Education of the People

In conclusion, Sir George Newman remarks that the relatively sound condition of the health of the English people at the present time should afford them both encouragement and gratification It is largely due to the steady progress which has taken place within the last two generations in their social life and habit Alongside an advanced and progressive policy of health reform on the part of the legislature, there has been steady progress in the administration of public health measures, as well as profound social changes For the masses of the people the hours of leisure have been extended, housing, clothing, and diet have improved, life has been lived more in the open air and more of its amenities have been enjoyed The practice of sobriety has come to appeal to them common sense, and they have taken a fuller and more reasonable interest in their own health and function He points out that the public health services have been a means, not only of providing facilities, but of actually educating the people The value of the public services must always be conditioned by the state of public education

On one matter, perhaps, the enthusiasm of Sir George Newman has led him to bestow praise which he might well have qualified He points to the newspaper press, with its millions of readers, as one of the most effective means of educating the people in the importance of health Newspapers, he says, constitute one of the principal exchanges for the enlargement of the mind of the public, and he continues "In recent years there has been an enormous extension and development of all classes of newspapers in the presentation, interpretation, and application of our knowledge of the science and art of hygiene Of its educational value there can be no doubt" It is true that some London and many provincial newspapers maintain a high standard of journalism, but it can hardly be denied that a large section of the "popular" press holds a distorting mirror up to current affairs, in health as in other matters, and often gives information which, if not inaccurate in detail, is false in emphasis Genuine news is sacrificed to "stunts", false hopes are continually being raised as regards alleged "cures," and scares are started which alarm the uncritical It is a question whether the tit-bits of health information given in such fashion do not at times create an ignorance more deplorable than that which they profess to remove

MEDICAL HYDROLOGY IN PORTUGAL

The annual meeting of the International Society of Medical Hydrology was held this year in Portugal from October 15th to 23rd, under the presidency of Dr Belo Morae, professor of clinical medicine at the University of Lisbon The society met in conjunction with the older organization interested in hydrology—namely, the Triennial Congress, founded at Biarritz in 1886, and now under the presidency of Professor Egas Moniz Nearly three hundred medical practitioners, from most of the European countries, took part in the proceedings

The congress and the society were received at the Academy of Sciences by the Prime Minister, Senhor Domingo Oliveira and Senhor Cordeira Ramos, Minister of Education In responding for the society, Dr Fortescue Fox said that in all countries the same problem was encountered, the use of waters and baths for invalids was everywhere on the increase, but the principles of hydrology were little understood Professor Egas Moniz announced that systematic lectures in hydrology now formed a part of medical teaching in Lisbon

Treatment of Digestive Disorders

The subject of the society's discussion was the treatment of digestive disorders by hydrological methods Dr Armando Narciso of the Lisbon Institute of Hydrology said that the alkaline waters of Vidago and Salus were employed for acid types of dyspepsia with pain and pyloric spasm, with or without latent ulceration, as well as for many hepatic cases For atonic or muco-membranous entero colitis both alkaline and chloride waters were prescribed Drs Mazeran and Aime (Châtel-Guyon), discussing chronic affections of the colon, clearly differentiated functional disorders from alterations in the mucous surface and colitis properly so called In the treatment of these various conditions the writers distinguished (1) waters acting directly on the colitic process, (2) those that acted upon the abdominal nervous system, and (3) those which acted primarily upon other digestive organs Among external applications, warm and sedative baths came first and then stimulant carbo-gaseous and saline baths Cold was carefully avoided, colonic lavage was reserved for exceptional cases, and then was used only in small quantities, *goutte à goutte* Dr Fred Kraus spoke from thirty five years' experience at Carlsbad of the treatment of slight jaundice, hepatic engorgement, early cirrhosis, and the various cholecystopathies All these types of subacute or chronic digestive disorder derived benefit from alkaline sulphated waters often combined with packs of hot peat, 60 to 70 per cent of his cases were relieved of all symptoms by such means In affections of the gall-bladder and bile-ducts they were the best alternative to surgical treatment and were also often very useful after operations Dr Zoltan Rausch (Budapest) considered that hydrological treatment was becoming more precise from the new knowledge of liver functions Thermal sulphated waters appeared to favour the excretion of bile in hepatic engorgement and abdominal plethora, but further investigation was required Dr Michael Foster dealt with the use of British waters in disorders of the digestive tract Experiment had shown that the old sulphur springs at Harrogate produced an increased flow of bile Such waters, with hot liver packs, gave good results in chronic congestion and slight enlargement of the liver, while the milder saline waters of Leamington and Llandrindod were indicated for other forms of hepatism Many tropical cases, for which a temperate climate was no real cure, obtained rapid relief from British sulphur or saline waters Dr Paul Weiss advocated the more general use of waters for the digestive disorders of children Chloride waters, especially those containing calcium, were, if judiciously used, of much service, and led to marked increase of weight, as had been shown in the home for children at Homburg Such springs provided the material for building up new cells, and regulated the water balance, they also diminished vagal tone and irritability of the central nervous system Children were often more successfully treated at the spa

by waters, with careful dieting, than at the seaside resorts, where dieting was too often neglected.

A paper by Professor Amaj (Andorno) dealt with the external treatment of gastric and duodenal disorders by hydrotherapy. Thermal and mechanical applications (sponging ablution, half-baths friction baths and douches) might be according to their temperature and technique, either stimulant or sedative and analgesic. When judiciously employed the results were excellent, but long experience and judgement were indispensable, since one error in technique might upset the whole course of treatment. Dr Fox like Dr Mazeran, emphasized the importance of studying the "chronic disorders of transit or traffic" in the digestive canal for which only gentle treatment ought to be prescribed. Both aperient" waters and large injections, when repeatedly given were irritating and injurious, and the *coup de mucus* should be regarded as a danger signal.

General Business.

The society's international standards measurements committee (chairman Dr S. Judd Lewis) presented a draft register which had been under preparation for three years. It suggested an agreed system for recording the composition and qualities of the medicinal waters of all countries also a provisional classification. This was *adopted by the society* subject to certain amendments. The society's committee on social hydrology (arrangements for the treatment of insured patients and their families) considered proposals from Germany (Dr Hirsch) and from France (Dr Durand Fardel). The report will be laid before the proper authorities *in all countries*. The committee on the protection of spas was reappointed.

Among the more important papers presented to the hydrology section of the international congress of hydrology climatology, and medical geology were an account of the variations in the blood during spa treatment (Professor Sarmento and others), experiments on the action of waters upon spasm of unstriated muscle (Professor Villaret and Drs Justin Besançon and Cascão de Anciães) the use of various waters in syphilis (Professor *Brito* and Dr Pierret), and a discussion by Drs *George Baudoin* and Piery of the physiological and therapeutic effects of the physical factors in climates.

After the meetings at the *Faculty of Medicine* the delegates paid a short visit to the spas and health resorts of Portugal including the marine health resort and thermal establishment at Estoril the beautiful hill station at Cintra, and the spas of Curia Luso Busaco and Vidago.

MALARIA IN THE NORTHERN ADRIATIC

A Clinical and Epidemiological Study

Some provocative questions about the transmission of malaria are asked by an Italian physician, Giuseppi Corradini who has been in practice for thirty-five years in Rovigno, on the east coast of the Adriatic twenty miles north of Pola. He contributes to the September issue of the *Archiv für Schiffs- und Tropen Hygiene* a clinical and epidemiological statement of his experience there since he was appointed district medical officer in 1895. For the first fifteen years he was concerned with treatment as well as with administration seeing about three-quarters of the malarial patients who in one year might number a dozen and in another 300 the case incidence seemed to be independent of the degree of prevalence of mosquitos.

About 5 per cent of the cases were of the quartan type the remainder being tropical or tertian. Rovigno a town of 12 000 inhabitants lies at the foot of a sloping tract of dry chalky soil where there are no swamp springs or permanent stream but only rain water lakes and ponds in which mosquitos lay their eggs. Viticulture is the chief industry but the rural slopes are almost uninhabited since malaria in the past ruined the farms. The peasants retreated therefore to the town for they knew that only during daylight were they safe on the farms. They are but little attacked now more lightly than in most malarial places. Few townsmen were attacked for the town was surrounded by cattle sheds which provided a protective screen since mosquitos prefer the blood of cattle to that of man. Early in 1915 the inhabitants were evacuated to Pola all but 400 (among these 25 peasant families) and all the cattle were commandeered and removed. A fortnight later the still remaining peasants were ordered to reside in the rural area in tents in August an epidemic of malaria compelled their return to the town now severely attacked since it had been deprived of its protecting cattle.

The three classical types of malaria occur in Rovigno now but all are mild and amenable to quinine. The *I. falciparum* infection is notably milder than elsewhere and causes no swelling of the spleen or initial rigor. There is also a quotidian form not a double infection but exceptionally mild its parasite *P. immaculatum* is according to D. Corradini smaller more delicate and much more numerous in the blood. In 1907 he found it in 38 of 51 tropical cases. Pernicious *falciparum* infections hardly ever occur. This persistent harmlessness is curious because every year 800 workers came to Rovigno from Apulia (where malaria is really malignant) for the brandy-distilling season in September yet the local mosquitos never seemed to become infected with the graver forms of malaria. Indeed severe cases were quite uncommon until 1915 when the railway watchmen who were continuously exposed at night began to suffer they were all local men so no new infection of the mosquitos could be alleged and there was as yet no food shortage. Since the war the cases have again become slight. The author defines two chief malarial seasons the spring (March–May) and the summer-autumn (August–October). The spring cases were tertian, including each year a quarter of those who in the previous year had had malignant tertian and were relapsing always with benign tertian. He thinks it impossible that in all these cases he had missed mixed infections he is sure his examinations (always a deep drop and two films) were too careful for that. The cases continued to show *P. falciparum* until apparent cure after three or four months of recovery the patient became ill again now with *P. vivax* in their blood. The spring cases are Dr Corradini believes either relapses due to altered parasites or infections dating back to the previous year with *delayed incubation*. Tertian infection never changes into the tropical form but may perhaps he suggests change into the quartan.

The autumn epidemic commences suddenly and rapidly rises to a peak sometimes almost a rapidly as influenza. Why is there such delay in incubation? The author has tried in June and July to find parasites in patients of the previous year but always without success. Whence did the mosquitos receive their infection? In Rovigno there was little malarial infection since the mosquitos could not get into contact with patients how then did the mosquitos maintain their infectiveness? He deduces that there must be some other intermediate host for the malarial parasite beside man. At Rovigno in 1910 a hundred healthy persons were turned on to the land in early June and remained well until early August when within a few days most of them were attacked. The reports from the Roman Campagna are said to be similar and Dr Corradini concludes that the mosquito-infecting role of the human carrier is too much stressed at present. He notes the care ever later taken after the war to prevent the infecting of the anopheline mosquitos of Northern Europe by patients returning from malarious districts the precautions were never successful everywhere and no epidemic occurred but he doubts whether the precautions adopted were responsible for this. Finally the author discusses the possibility of infection arising from latent malaria of old standing which has long been present but has never diagnosed one limit of which is the presence as plasmodia pigment in post-mortem blood while tiny parasites polychromasia are absent from the blood. Of the methods of the symptoms by quinine is an important aid in making a diagnosis of malaria.

His ultimate conclusions are three (1) there is latent tertian but only relapses originate from latent infections of previous year (2) there is latent malarial parasitism in various forms and (3) there is an intermediate host of the malarial parasite other than man. It follows that the additional systematic malarial campaign must be concentrated on the mosquito if success is to be achieved.

Scotland.

Treatment of Scottish Blind

A REPORT of the proceedings of the Scottish Advisory Committee on the Welfare of the Blind to the Department of Health for Scotland, covering the years 1928 and 1929, has just been issued. The committee reviews the various arrangements that have been made by county councils in different parts of Scotland for the welfare of the blind, and criticizes the schemes which have been drawn up for the payment of grants towards setting up blind persons in business or employment. It is pointed out that the grants paid by the Department of Health towards services for the blind in 1927–28 amounted to approximately £18,000, that £53,000 was contributed during the year by local authorities to voluntary associations helping the blind, and that the total subscriptions, donations, and legacies received by voluntary associations in the year amounted to £37,681. According to the investigations of the committee the number of blind persons undergoing a course of technical education increased from 150 in 1921 to 386 in 1928, while the number of trained blind workers in institutions rose from 608 to 694 in the same period. The number of untrained blind persons stated to be capable and willing to undergo training in 1928 was only 135. Among the recommendations made by the committee is that in the administration of their schemes local authorities should in every case utilize the experience of those who work among the blind, and that they should take steps to provide adequate accommodation for aged and infirm blind persons who are not otherwise properly cared for. Contributions of local authorities towards the funds of voluntary associations should be on a per capita basis, on the lines on which grants are paid by the department. Every local authority should satisfy itself of the adequacy and efficiency of arrangements made in its area for the medical certification of blind persons. Further, no blind person should require to have recourse to the Poor Law for assistance, and in the absence of complete State provision for the maintenance of blind persons, local authorities should augment their incomes to 25s. per week, with safeguards against the refusal to work or be trained. A State compensation allowance, amounting to £1 per week for all blind persons over the age of 18 whose annual income does not exceed £105, is recommended. This graduated allowance would cease if the blind person's means amounted to £200 per annum. It is estimated that the annual cost to the State of a compensation allowance on this scale would be about £450,000 for Scotland. The net cost to the State, however, after allowing for the present expenditure of £120,000 on pensions to the blind under the Blind Persons Act and the Old Age Pensions Acts would be £330,000. The committee states that the institutional side of blind welfare work has been so well developed that the facilities for technical education and workshop employment of blind persons in Scotland are greater than in any other country. At the same time, it does not consider that the same high standard has been reached in ensuring the welfare of blind persons who are not suitable for institutional treatment. The report states that over £1,000,000 has been expended by the State, local authorities and education authorities in the past eight years on the welfare of the blind. The number of blind persons registered by the Department of Health for Scotland, as on April 1st, 1929, was 8,518—an increase of over 100 per cent. in the past ten years, and equivalent to a rate of 1·7 per 1,000 of the population. Of the registered blind, 69 per cent. are recorded as unemployable. The main cause of the increase in the number on the register is thought to be the more complete registration of blind old age pensioners, it is considered that a stricter and more uniform standard of certification of blindness is desirable. In the past ten years the number of blind infants under 5 years of age has been reduced by 71 per cent., the decrease in the number of children between the ages of 5 and 16 being 16 per cent. These figures confirm the beneficial effect of the measures carried out by local authorities for the prevention and treatment of ophthalmia neonatorum and similar diseases. The report is published by H.M. Stationery Office, George Street, Edinburgh, price 9d. net.

Future of the Family Doctor

Dr. Charles Forbes delivered his presidential address before the Aberdeen Medico-Chirurgical Society on October 30th, taking as his theme the place of the family doctor in the supply of an adequate medical service for the wage-earning and poorer classes in the Aberdeen region and the North of Scotland. He made a brief survey of the growth and development of the public medical services, dealing particularly with the Poor Law, dispensary, public health and compulsory insurance services. He directed his remarks mainly to the members in general practice, impressing upon them the seriousness of the present situation in Scotland, and outlining what he considered to be their position in relation to the preventive-curative work carried on through the public health clinics and the dispensary. The public demand was insistent for an adequate service. He saw only two ways of meeting this demand, either by an extension of the services given through the public clinics to include domiciliary treatment of the families, or by an extension of the existing insurance services to include the wives and dependants of insured persons and allied classes. Dr. Forbes urged his fellow practitioners to fight for the acceptance of the policy of the organized medical profession, both for the benefit of the common folk and for the future of general practice in this country.

The Health of Workers

Under the auspices of the Department of Social Study and Training of the University of Edinburgh an address was delivered on November 4th by Lieut.-Colonel Sir Arnold Wilson on the *promotion of health in industry*. Principal Sir Thomas Holland, who presided, remarked that the knowledge and conditions affecting good work had improved very greatly since the war. Sir Arnold said that Great Britain had been the first country to promote factory legislation, but the solid advances that had been made had seldom originated in political programmes. Progress had been achieved almost entirely as the result of the study and systematic work of factory inspectors and medical officers, and the promotion of health in industry had largely depended on medical research. One of the most successful methods of reducing industrial fatigue was to study the movements of the worker. This study had originated in America, where it was carried on by engineers with the object of increasing output. The most economical movements had been standardized in regard to time, and output of work had consequently been increased, this increase, however, was due mainly to increased speed and not to real lessening of fatigue and such methods had aroused resentment among the workers. The problem in this country had been approached from a different angle by psychologists, not by engineers, and principles which were more fundamental had been discovered in relation to economy of movement. The methods devised had been to make the movements fit into the natural rhythm of the worker. Rest pause in working periods had been introduced into various occupations with great success. The incidence of accidents had also been studied in relation to hours of work and atmospheric conditions. The question of the proper length of the working day was constantly being examined. Long hours of work were found to be uneconomical, because they caused undue fatigue and lowered the hourly output. On the other hand, the shorter working day enforced in collieries had had the effect of reducing the total output, and no amount of speeding up could compensate for hours shortened beyond a certain point. Further, short hours and high speeds tended to penalize older workers, who could perform tasks more comfortably when spread over a longer period. Short hours often *meant that expensive* machinery was out of use for long periods, and this led to demands for double shifts, which disorganized domestic arrangements. They were now entering upon a new economic era. This country had a tradition of loyalty, fair dealing, and craftsmanship, and the chief concern of those whose business it was to promote health in industry

was to emphasize the importance of the human factor Psychology was a young science, but it was based on sound principles and its application to industry would do more to refashion civilization than any Acts of Parliament

Medicines, Old and New

A lecture on medicines, old and new, was delivered under the Combe Trust in Edinburgh, on November 5th, by Dr *John M Bowie Lord Sands*, who presided, remarked that in older days he thought that there was more knowledge of medicine *in the household* than at the present day Dr Bowie said that the earliest medical records were found in Egypt and dated about 4000 B C Medicine at that time depended mainly on the theory that disease was possession by an evil spirit, and the practice of healing consisted largely of means directed towards exorcism Later, these oral rites were accompanied by manual rites, such as that of tying a knot seven times, later still, the manual rites developed into giving the patient some substance, often of an obnoxious nature, to hasten the departure of the spirit In time, by a process of exclusion some of these substances were found to be of real value, and thus the profession of medicine and the use of medicines to cure disease had arisen About 30 per cent of the drugs in the present pharmacopoeia were known to these later Egyptian physicians, including such substances as castor oil, dill, turpentine, and myrrh Greek medicine from the sixth century B C to the second century A D had left a legacy of clinical observations The Greeks had a strong belief in the healing power of nature After a period of suspended animation in medicine, which lasted till the sixteenth century, the medical schools arose and from that time medicine had steadily developed The present age of medicine might be said to have begun in the middle of the eighteenth century, when the idea of prevention came into being to combat the epidemics and the high infantile mortality *which was then brought about* by the overcrowding of the towns during the industrial revolution The present era of *scientific subdivision or specialism* began in the early part of last century, and since then biochemists had given us *the endocrine extracts, and* bacteriologists the vaccines, but it was well to remember that new remedial agents such as *x* rays, ultra violet rays, radium, and so on, were only in their infancy, and the statements of miraculous powers *sometimes attributed* to them should be treated with due reserve The other measures prescribed by the doctor were usually of more importance than medicines, although fashions in medicine would probably tend in the future, as in the past, to hinder rather than to help the progress of the healing art

Education of the Deaf

The Educational Endowments (Scotland) Commission has *drawn up a scheme* under the Educational Endowments (Scotland) Act, 1928, for the amalgamation of Donaldson's Hospital, Edinburgh, and the Edinburgh Royal Institution for the Education of Deaf and Dumb Children, with a view to the better education of the deaf The former of these institutions was inaugurated in 1845, and the latter in 1816 The Commission proposes to establish a governing board of twenty three persons to be elected by various bodies, in order to administer the united institution and its property At present half of the children at Donaldson's Hospital are deaf and dumb while the others are normal but necessitous children The scheme directs that the education of normal children shall in future be discontinued all the resources of the two institutions being devoted to the education of the deaf and dumb A school is to be set up in Donaldson's Hospital to be known as Donaldson's Royal Edinburgh School for *the Deaf* and boarding-houses for the children are to be established as they may be found necessary When the boarding-houses are ready the buildings of Donaldson's Hospital will cease to be used for residence and will be devoted entirely to the purposes of the school Arrangements are to be made for the provision of a nursery school department a department for general education and a department for vocational training Children will receive a general education up to the age of 16 years and education of a vocational type from 16 to 19 Parents or guardians, and *town and county councils and other* public bodies, may arrange for the education of their deaf and dumb children at the school on payment of fees Arrangements are also proposed to make the school available *as a clinic in the event of a course* on education of the deaf being instituted in the University of Edinburgh Copies of the draft scheme may be obtained from H M Stationery Office, 120, George Street, Edinburgh, at *the price of 5d*

Royal Medical Society of Edinburgh.

An address on the prevention of cancer was delivered to the Royal Medical Society of Edinburgh on October 24th by Mr W Sampson Handley, *surgeon to the* Middlesex Hospital He said that one person in every seven who reached the age of 30 ultimately died of cancer so that the subject was of immediate public interest Cancer starting *in accessible positions might be regarded* as a local and curable disease if detected at an early stage, and even if the patient sought advice too late for cure, much could be done nowadays to delay the fatal issue by radium treatment and other methods In the last half-century the average duration of life had increased by ten years this fact might be associated with the higher mortality from cancer occurring to a large extent in people who, but for the *development of medical knowledge, would* have died in youth The Middlesex Hospital had issued a series of health leaflets for the instruction of the public in health matters, and several of these dealt with cancer The routine medical inspection of middle-aged persons at regular intervals would in many cases lead to the detection of early cancer while it was still curable, he considered that this was the best practical policy for controlling the disease The general belief that the cause of cancer was absolutely unknown was no longer true *in his opinion*, for according to his observations malignant disease *occurred only in areas of tissue* where the lymphatic vessels had been blocked by previous local disease, cancer could be almost abolished if it were possible to prevent chronic inflammation of the lymphatic vessels

England and Wales.

Halley Stewart Lectures.

The Halley Stewart trustees invited Sir George Newman to deliver their course of lectures this year and he chose as his subject, 'Health and social evolution' the opening lecture, on "How England learned to control disease" was devoted to a consideration of the social structure of England in the Middle Ages and its relation to modern institutions particularly those concerned with health The manor estate and its justiciary courts, the monastery as the local centre of learning and institutional religion and the guild as representing industry were discussed and it was shown that their joint services were the beginning of co-operation national tradition, self-government and public service, including health services Upon this social structure the Black Death broke in 1349, not only disorganizing it but so changing it as to destroy half the population, redistributing poverty and wealth changing *the course of agriculture, and affecting wage rents* taxes and tenure It also domesticated foreign pestilence on home soil, and so resulted the first *organized attempt* at preventive medicine The lecturer then discussed medical practice in *England from the time of the Conquest* to the end of the eighteenth century and showed the part played in England by the doctor and by the former of the Renaissance, including Sir Thomas More Finally the lecturer touched on the rise of individualism and humanitarianism in the eighteenth century In the second lecture, entitled Health problem of the modern period Sir George Newman discussed the nature of man and its relation to nurture, environment and ignorance going on to show the changes in the incidence of disease between the two periods before and after the eighteenth century the former being marked by famine pestilence plague and ignorance, and the latter by a group of deficiency diseases,

infections, and impairments There was one new enemy—namely, the vast increase in population Up to the end of the seventeenth century the population never rose beyond about 8 millions, but in the nineteenth century it rose to 32 millions, which had since increased to 38 or 39 millions The lecturer considered that from a health point of view the industrial revolution formed the Great Divide between the old England and the new England, between a rural England and an urbanized England, and between a small and scattered population and a large dense one The industrial revolution not only led to increase of population, and to its redistribution but also to new housing and factory problems, involving radical dealing with factory reform, housing, and the physical welfare of women and children The modern period was also marked by the coming of democracy, and a new spirit which manifested itself in a demand for municipal reform, increased franchise, co-operative movements of various kinds, utilitarianism, and the creation of a vocal public opinion and an insistent demand for the application of social medicine

Reconstruction at Great Ormond Street

It has been determined to proceed at once with a scheme, long overdue, for the reconstruction and modernizing of the Hospital for Sick Children, Great Ormond Street The hospital was founded nearly eighty years ago, and has been enlarged three times by piecemeal additions It began as an affair of ten beds in a house which even then was old, having been the house of Richard Mead, the eighteenth century physician It is interesting to recall that one of the sponsors of Great Ormond Street was Charles Dickens, who lived at that time at Tavistock House, less than half a mile away, the site of which is now occupied by the headquarters of the British Medical Association The idea of a children's hospital appealed to Dickens's fervent imagination and love of children, he described the hospital in *Our Mutual Friend*, and spoke in public on its behalf The hospital has now grown to 252 beds (with 45 at the branch hospital at Tadworth) and it is claimed that its beneficent work as the prototype of children's hospitals throughout the world has resulted in the restoration to health and happiness of more than a million and a half little children Although aware that other hospitals are making similar appeals, the board of management, with Lord Macmillan in its chair, has decided that matters cannot wait any longer, but that the hospital must proceed at once to remedy by a comprehensive scheme the present state of congestion, which is detrimental to the full efficiency of its work The Prince of Wales, who is president of the hospital, has commended the project and the necessary appeal and is attending a meeting at the hospital on November 19th with the object of furthering it

Medical Women's Federation

The half-yearly meeting of the council of the Medical Women's Federation was held on October 31st and November 1st at the London (Royal Free Hospital) School of Medicine for Women, with the president, Miss Martindale, in the chair Among matters discussed was the need for the appointment of more women doctors on the staffs of mental hospitals, women patients being in a preponderance Some discussion took place on the question of the sterilization of mental defectives Dr Doris Odlum presented an interesting report on the Mental Hygiene Congress recently held at Washington, which she attended as a delegate from the Federation A discussion took place on birth control and the possibility of obtaining exact information thereon Satisfaction was expressed at the lifting of the ban on the admission of women medical students to King's College Medical School London It was hoped that other medical schools would follow the good example Considerable discussion ensued on the need of facilities for medical women to obtain post-graduate instruction in medicine and surgery and special subjects in London, these specialized courses being necessary for the obtaining of the higher qualifications, such as F R C S and M R C P It was realized that the facilities for post-graduate study provided for men were often inadequate and restricted, but it was felt that an effort should be made to secure that when courses were arranged they should as far as possible, be available to men and women alike The London Association presented its report on dysmenorrhoea, an analysis of some 6,000 cases This investigation which had taken five years to complete, was welcomed as a fine piece of exact scientific work Dr Helen Chambers gave an interesting account of the work done at the Marie Curie Hospital as exemplifying what could be achieved by the organized efforts of medical women working on one definite method at one aspect of the cancer problem It was announced that a new unit had been started in Edinburgh to link up the work of medical women in Scotland, guided by the experience of the workers at the Marie Curie Hospital Dr Helen Chambers suggested that, in order to extend this work in England, other units staffed by medical women might be linked up with the Marie Curie Hospital by means of a travelling radium specialist

New Turkish Baths at Eastbourne

Dr R Fortescue Fox opened the new Turkish baths at Eastbourne on November 7th The total cost of reconstruction and of introducing new equipment has been over £9,000, the new building includes a cooling room, three hot rooms, a massage room, a plunge bath two vapour baths, and a Russian bath Dr Fortescue Fox emphasized the importance of spreading information about the curative properties of the seaside He believed that in future the sea would play a more prominent part in therapeutic Coastal health resorts should utilize all their natural resources, and should introduce the various artificial procedures which were now being devised since in such a variable climate as that of England heat treatment would always have its part to play Some forms of hot vapour baths had been used in northern climes for several hundred years, and it was only in England that this method of treatment had somewhat fallen into disuse in the past It had been revived here about one hundred years ago and was now recognized as one of the most important ways of treating rheumatism

Correspondence.

DRAINAGE IN PLEURAL EFFUSIONS

Sir,—May I, as one of the surgeons so gently prodded by Dr R A Young in his most instructive paper on the medical aspects of thoracic surgery (*Journal*, November 8th, p 763), proceed in return to cavil at one of his paragraphs? It is that one in which he mentions the report of the American Empyema Commission and then goes on to state that a streptococcal pleural effusion should never be drained till frank pus is present Surely the moral of that report was that the indication for open drainage should be the state of the patient rather than that of the effusion, the crucial point was not whether the fluid was thick or clear, but whether the lungs had recovered sufficiently from the original pneumonia to stand the interference with their action caused by a free airway into the pleural cavity On the other hand, I do not see why any patient should be better off with streptococcal fluid in his chest than without it, provided that it can be removed without upsetting him by means of a needle or "closed drainage" tube

However, *on considering that* "sup pneumonic empyemas are usually streptococcal, that streptococcal effusions usually remain clear in their early stages when they are likely to coexist with a pneumonia, and that operations on them in this country usually involve the resection of a rib under general anæsthesia, I must admit that Dr Young's warning comes to much the same thing in the end I must also admit that the trouble with the closed drainage methods comes later, but that is another story —I am, etc ,

DENIS BROWNE

London W 1 Nov 8th

TEMPORARY TREATMENT WITHOUT CERTIFICATION

SIR,—The new Mental Treatment Act comes into operation on January 1st, 1931, and, as is now well known, one of the most important provisions it contains is that relating to the temporary treatment of patients without certification It has, I think, been generally accepted that the intention of the promoters of the Act was to enable treatment of early and recoverable cases of mental illness to be obtainable without recourse to a justice's order The main section of the Act dealing with this provision states that, in addition to the fact that the patient must be suffering from a mental illness and be likely to benefit by temporary treatment, he must also be "incapable of expressing himself as willing or unwilling to receive such treatment" Now does this mean what it says? If, for example, a patient otherwise suitable, says that he is unwilling to enter an institution for treatment, as most are likely to do does it mean that this patient must be certified? Or is the section meant to imply that, even though the patient expresses his unwillingness to receive treatment the doctor is entitled to decide and base his recommendation on whether the patient understands what he is doing at the time? If so, the section is very badly worded, and is likely to lead to much confusion in practice An authoritative ruling on the point is urgently desirable—I am, etc,

London W.1 Nov 7th. FREDERICK DILLON

THE CRADLE OF ANTISEPTIC SURGERY

SIR—In a recent issue of your valuable *Journal* I noticed a slight error, which I think should be corrected It was to the effect that the antiseptic methods of surgery first made their appearance in the Edinburgh Royal Infirmary I yield to nobody in my respect for the Edinburgh School It is one of the best schools in the world, and for a very long time has maintained its high reputation combined with excellent work

At the same time Lord Lister was not in Edinburgh when he first began modern surgery He was a London man and he came to Scotland for the purpose of studying Edinburgh surgery, particularly with Syme, whose daughter at a later period became Lord Lister's wife There was a vacancy in the chair of surgery in Glasgow in the early sixties of last century for which vacancy Lister successfully applied He got wards in the Glasgow Royal Infirmary and first introduced antiseptic surgery into these wards Lord Lister was a very highly cultured man, and intensely sympathetic and he was appalled at the number of deaths which took place in his wards

He brought the matter very prominently before Dr Anderson who at that time was professor of chemistry in the University of Glasgow although he was professor of chemistry Dr Anderson had a medical qualification, and was a widely read, highly cultured man It was he who pointed out to Lister Pasteur's researches on the effects of micro-organic action Dr Anderson suggested that probably that was the cause of the high death rate, and to him also was due the suggestion that carbolic acid might prove the remedy for the trouble Dr Anderson being professor of chemistry had no wards and no practice whatsoever, but Lister at once put the matter to the test and found that his colleague Anderson was quite correct Some of the apparatus which was used in the Royal Infirmary of Glasgow such as the carbolic spray was in existence only a few years ago and so far as I know may be in existence yet

Nothing more unfortunate could possibly have occurred than the destruction of the Lister ward As recently pointed out by myself in the columns of the *British Medical Journal*, the whole of the directors of the Glasgow Royal Infirmary were not on the side of the Huns a third of those who were at the meeting which determined the disaster were anti Huns and at the last meeting I had the honour of leading the forlorn hope

It may be mentioned that probably the first place in the United Kingdom if not in Europe where the change from antiseptic surgery to that modification of it generally called aseptic surgery took place was the Royal Infirmary of Glasgow, and the surgeon who made that change was William Macewen

No person acquainted with the facts has the lightest wish to lessen the glory of the Edinburgh School or to disparage it but at the same time although it has probably done more than any other school in Scotland to advance medicine, still, when valuable contributions have been made in other school, I think the facts should be accurately stated—I am etc,

Rothesay Nov 3rd. FREELAND FERGUS

IONIZATION IN ULCERATIVE COLITIS

SIR—The letter of Dr Curtis Webb in your issue of November 1st (p 757) commenting on my article on this subject, whilst impressing me with my negligence in not searching the literature, enhances the value of my own contribution In 1905 he writes to the *Lancet* in general terms on "electric enemata," and in 1911 he adduces in support of this nineteen cases of colitis (including mucous colitis) which were all treated successfully with zinc ionization Had I known of his work I should certainly have made mention of it, and indeed, should not have delayed publication of my own results for so many years—a delay partly arising from doubt as to the efficacy of so simple a treatment in so serious and intractable a disease and partly from a desire to collect sufficient evidence

In recent publications and discussions on ulcerative colitis no mention is made of electrical treatment When I showed my first case in 1924 before the West London Medical Society Mr Aslett Baldwin confirmed my result from his own experience in dysenteric cases I did not include any cases of mucous colitis in my series, as the few cases I attempted were unsuccessful But in the light of Dr Curtis Webb's work I shall repeat the treatment at the first opportunity In chronic dysentery, also I should like to try ionization, but no doubt others with more opportunity will do so

One other criticism has been made to me which bears on the very premisses of the matter Does the ionization act throughout the entire length of the colon or is the good result due solely to lavage with zinc sulphate? Dr Curtis Webb answers this as I do, that his first case failed to get relief with silver nitrate lavage until combined with ionization Dr Carter Braine has further tested this point for me in a case with a colotomy opening and has shown that there is some current flowing in the fluid from the colostomy wound This is a point I must leave to the physicists for I cannot reckon myself among them My interest lies in the fact that numerous cases of ulcerative colitis occur especially among women and these are amenable to ionization

Finally I should be grateful to know of the results of more extensive tests of the treatment which I understand is being tried for with increasing experience one recognizes the limitations of all treatments and doubts will continue to arise—I am etc

London W1, Nov 4th. JULIUS BURNFORD

PERSONNEL OF A RADIUM CLINIC

SIR—I was pleased to see in the *Journal* of November 1st a letter from that doughty champion of the professional radiologist, Dr Douglas Webster With him I may sometime cross swords on minor matters but always find myself in agreement on main issues His remarks are of especial value as he makes it clear that owing to his having at his disposal six beds at the Middlesex Hospital, he is not suffering under any sense of personal grievance I think this is very important as letters which give the impression that the writer is smarting under a sense of injustice to himself seldom carry much weight even if the arguments contained in them are sound For this reason I would preface my own remark by saying that in the hospital to which I am attached nearly all cases of malignant disease are sent to me within a few days of operation and in an increasing number of instances for a preparatory course before operation is undertaken Although I have no special beds, I have no difficulty in getting on when I wish and from time to time I have cases in hospital which are receiving radiation treatment alone Also, the radium

supply, while of course freely available for surgical use, is under my immediate charge

Now for a tilt at Mr Duncan Fitzwilliams and such surgeons as approve his attitude It is less than ten years since I heard Mr Fitzwilliams publicly declare at a meeting of the Chelsea Clinical Society that x rays and radium should be classed with violet leaves among the quack remedies for cancer of the breast I must, of course, congratulate him on his conversion so far as radium is concerned, but I am not impressed with his competency to act as a judge with regard to the results of x-ray treatment

As Dr Webster points out, material for a comparison of the results of x rays and those of surgery in early operable cases scarcely exists as yet in this country Statistics are beginning to be available in breast cancer with regard to surgery alone, and radium treatment alone, but this is only because the latter treatment has been chiefly interstitial, and so has been carried out by the same people who formerly did the radical operation On the other hand, cases with widespread recurrence are sent to the x-ray department, and the extraordinary thing is that most of these patients are kept going in comparative comfort for months, and often for years, and that a few of them may even be regarded as "cured" in that, becoming free from signs and symptoms, they cease to attend in spite of orders, and when subsequently traced years later are found to have remained in good health

Some of the most remarkable results in modern medicine—to which the overworked adjective "miraculous" might well be applied—are seen in the deep x-ray treatment of inoperable cancer of the uterus with invasion of the pelvis I have myself published two such cases in which patients, admittedly dying, were restored to active life, in one case for ten months, and in the other for a year, during which periods there were no symptoms Precisely the same arguments which have led to the use of radium alone in cancer of the breast, uterus, and tongue can be employed to advocate deep x rays as a substitute for operation in cancer of the cervix On the Continent such treatment has been extensively carried out, with results at least equal to those of panhysterectomy

Apart from the opinions of a few people who are of Mr Fitzwilliams's way of thinking, there is general agreement that x rays can powerfully affect for good many forms of cancer Concerning the value of radium, there is now little dispute, and surgery, of course, has a well-established place Surely it is most unscientific to be a violent partisan of one form of treatment to the exclusion of one or both of the others X rays have many inherent advantages, they can be produced in practically unlimited quantities, and thus evenness of distribution can be secured over as wide an area as may seem desirable They are available in any well-equipped hospital, whereas the radium supply of the world is at present quite inadequate to deal with a tithe of the cases requiring treatment

On the Continent at the present time there is a strong movement in favour of combining localized interstitial radium treatment with wide external irradiation by x rays, and in such matters what the Continent is doing to-day England is pretty sure to be thinking about to-morrow The older radiologists in this country have been treating cases of malignant disease for over twenty years We have, each of us, seen more individual cancer patients than the average surgeon, we have seen each patient far more often, and we have seen them at a far worse stage of their disease Attempts to freeze out radiologists from participation in the treatment of cancer, or even to keep them in a subordinate place, may succeed for a time, but are doomed ultimately to failure—I am, etc,

London W 1 Nov 2nd F Hernaman-Johnson

IMMUNIZATION AGAINST TUBERCULOSIS

Sir,—I am whole-heartedly with Professor Calmette in his desire to immunize every infant against tuberculosis, but I am in complete disagreement with him about his method In the case of human beings immunization with a live antigen is very undesirable, if there is any alternative, since, while it protects the majority, it is invariably associated with the infection of exceptionally susceptible individuals, and there is always the risk of infection with contaminating microbes

Professor Calmette is quite wrong in stating that people are not afraid of small-pox vaccination, the very partial state of vaccination in the British Isles demonstrates the contrary Was there not a disaster with Haffkine's plague prophylactic similar to that in Lübeck, and is there not constantly a percentage of deaths in flocks given Pasteur's anthrax vaccine? Moreover, Pasteur's antirabies method is not free from suspicion of having caused some cases of the disease

The work of Wright, Leishman, and their co-workers has amply demonstrated the power of dead antigens against such assaulting epidemic infections as the enteric dysentery, and cholera In the case of tuberculosis such high tide of immunity is necessary to protect, since in nature the infection is of relatively slow incubation, and normal resistance overcomes it A dead antigen can, with very few exceptions, assure this, and there can be no danger of either the development of the injected tubercle bacilli or of contaminating microbes

Professor Calmette and others seem to forget that here we seeking to prevent against a natural infection, and not against a large infection by virulent microbes injected into the body In twenty years' work I only know of two cases of members of tuberculous families in which inoculation with my own "H T S" was not sufficient to prevent the disease developing I pray that there may be no further stumbling-blocks in the path of this essential method of prophylaxis—I am, etc,

University College, Dublin, Nov 10th W M Crofton

CONGENITAL RADIO-ULNAR SYNOSTOSIS

Sir,—I am obliged to Mr David J Davies for furnishing me with references to two articles on the above subject which had escaped my notice Your space is too valuable for me to go into their merits, but I should be obliged if you would allow me to clarify one point Mr Davies quotes John Fraser as saying that 'pronation varies from 90 to 120 degrees," and Mr Davis takes this to be contrary to my assertion that any degree of rotation (he misquotes me as saying "any degree of pronation") completely precludes the presence of a synostosis I am quite sure that what Mr Fraser means is a "*position*" of pronation varying between those angles, and not a '*movement*" of pronation In my original letter I clearly differentiated between these two by using the words "can be rotated through an angle"

I should very much enjoy seeing Mr Davies's case, as I think his description and photographs would fit very well a case of congenital dislocation of the head of the radius but would fit badly a case of congenital radio-ulnar synostosis—I am, etc,

Liverpool Nov 10th B L McIlreavy

Obituary

We regret to announce the death of Mr Hugh Davies which took place at Templecrone, Westcombe Park, Blackheath, on November 5th Born in February, 1867, Mr Davies spent his schooldays at Oswestry, after which he proceeded to University College, London, and Guy's Hospital, whence he qualified M R C S and L R C P in 1893 After graduating M B and B S Lond, with honours, and obtaining the gold medal for surgery in his year, he became house-surgeon at Guy's Hospital, and obtained the diploma of F R C S Eng in 1896 He settled in private practice at Greenwich and Blackheath, and in 1900 became an honorary surgeon on the staff of the Miller General Hospital, Greenwich, with which he was connected at the time of his death, being then senior surgeon After extensive experience in general practice, he established himself as a consultant surgeon in Harley Street In addition to his services to the Miller Hospital, Mr Hugh-Davies was also consulting surgeon to Camberwell House, Peckham, medical referee to the Prudential and other assurance companies, and a Fellow of the Hunterian Soci

nd the Medical Society of London He was also a ember of the Greenwich Division of the British Medical ssociation In Greenwich and Blackheath Mr Davies will e much missed by his numerous friends who esteemed him oth for his work and for his personality and undoubtedly ie community has sustained a great loss He is survived y his widow, whom he married in 1900, and by three ildren

Dr CECIL FRANCIS WATTS who was drowned in the hannel on November 2nd while yachting, was born in 02 and received his early education at Sherborne and inity College, Cambridge After gaining first-class honours i both parts of the Natural Sciences Tripos he had an ually distinguished career as a student at St Bartholoew's Hospital winning the Sir George Burrows prize i pathology, the Skynner prize in regional and morbid natomy, and the Willett medal in operative surgery, and eing ranked *proxime accessit* for the Brackenbury scholarhip He graduated M A and B Ch Camb in 1927 and ntained the diplomas M R C S L R C P in the same ear He had held at his hospital the appointments of inior demonstrator in pathology, casualty house-physician nd house-surgeon and clinical assistant in the surgical rofessorial and the orthopaedic units he had also been asualty officer at the Miller General Hospital Before ualifying he published a paper in the *Proceedings* of the 'hysiological Society on the relation between the size f the electrical response and tension developed during he contraction of striated muscle and also another paper n the effect of curari and denervation on the electrical xcitability of striated muscle In 1929 he contributed to t *Bartholomew's Hospital Journal* an article on fractures of the tibia and fibula with notes of five cases He was a member of the British Medical Association

Dr WILSON BLACK, who died on October 23rd at his esidence in Academy Street, Inverness, had been in ill-ealth since he retired from active practice about seven ears ago John Wilson Black received his medical educaion at Edinburgh University where he graduated M B, M in 1885, and proceeded M D in 1896 After acting is house-surgeon to the Northern Infirmary Inverness he as appointed a member of the medical staff as ophthalmic urgeon His skill in the treatment of eye diseases was oon recognized when he started practice in his native own, and patients came to consult him from a wide area s a family practitioner he had a large and influential ractice being much beloved for his sympathetic and nassuming disposition Dr Black was a member of the phthalmological Society of the United Kingdom and f the Scottish Ophthalmological Society

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

HE House of Commons this week considered the Covern ent's Agriculture Bill and the financial side of the proposal raise the age for compulsory school attendance

The Parliamentary Medical Committee at its first meeting the session on November 11th re-elected Dr Salter its airman and Mr Somerville Hastings its honorary secretary selection was made of subjects on which addresses or dis sions are desired at future meetings Suggestions approved clude Dr Addison on bovine tuberculosis an address fr m spoke man of the Eugenics Education Society and talks n lonal medical problems health problems in mining the health the mercantile marine and maternal mortality

A committee of the National Medical Service Association at the House of Commons on November 10th and approved modified draft of a statement in criticism of the British dical Association Scheme for a General Medical Service his criticism will be published

The Conservative party's Parliamentary Agricultural Committee has appointed a committee to investigate the present sition of the Royal Veterinary College

On November 7th the Architects Registration Bill was read second time without a division During the debate Professor clair referred to the General Medical Council and spoke of the improvement in the dental profession which had followed registration under the Dentists Act 1921

The Education (School Attendance) Bill was read a second time on November 6th Speaking against the second reading Dr Vernon Davies said he was assured that the little pieceers of Lancashire were no poorer as their fathers owing to the abolition of the half time system

On November 11th Mr Foot presented a bill to extend the operation of the enactments relating to the protection of animals kept in captivity or confinement and released for the purpose of being hunted or coursed

B.C.G.

Mr CREEWOOD in reply to Mr Freeman on November 6th said that he had received a copy of a confidential report made to the Medical Research Council by the two representatives who visited Lubeck early this year in connexion with the deaths of sixty-seven children following the Calmette treatment at the Pasteur Institute The report dealt with technical matters which were of interest only to research workers and did not cover the ground of the official German inquiry which was being made by the Imperial Board of Health By courtesy of the German authorities he had received copies of two statements on the subject in one of which mention was made of the neglect of certain precautions which should have been observed in the administration of the treatment but the investigation into the cause of the deaths which involved difficult problems of bacteriology was not complete and might not be completed for some time

Animal Experiments.

Mr SHORT said in answer to Mr Freeman on November 5th that members of the advisory committee for the administration of the Acts relating to experiments on living animals were appointed on the ground of their general suitability to advise the Secretary of State There was no differentiation of function between various members of the committee The usual method of killing animals found to be suffering pain which was severe or likely to endure was to administer an overdose of chloroform but no record was kept of such cases

Mr CLYNES said on November 11th that the evidence for scrupulous observance of the pain condition in experiments was that the inspectors who saw many thousand of animals under experiment in a year had not found any infringement of the condition The known character of the licence holder was an additional guarantee that the conditions of their licences were observed He would not arrange for a summary to be included in the annual official report of the nature and purpose of each experiment performed on living animals To do so would be foreign to the purpose of the report and an unjustifiable expenditure of public money No useful purpose would be served by keeping a record of the number and species of animals killed following vivisection experiments as a result of pain which was too severe and likely to endure and publishing the figures in the annual report

On November 11th Mr SHAW told Mr Freeman that no experiments had been carried out on horses at Cambridge and those at Porton had been with the sole object of devising protective and curative treatment for these animals Dogs were not used for experimental purposes at these stations

Control of Dangerous Drugs.

Mr CLYNES told Colonel Howard Bury on November 6th that all States whether members or non-members of the League of Nations would be invited to send representatives to the general conference being convened next May or the conclusion of an agreement on the limitation of the manufacture of dangerous drugs The Preliminary Opium Conference now taking place was convened to consider questions which concerned primarily those countries engaged in manufacturing dangerous drugs in preparation for the general conference in May 1931 to which all consuming countries were being invited

Mr CLYNES told Mr Maxton on November 5th that no final action was required concerning the traffic in opium and other dangerous drugs as recommended in a resolution passed by the League of Nations The measures recommended were already in operation in this country

Dental Benefit.

Answering Mr Llewellyn-Jones on November 6th Mr CREEWOOD said about 6 000 approved societies' branches in England and Wales whose total membership at the date of the actuarial valuation was approximately 12,750 000 contributed towards the cost of dental treatment for their members and about 500 societies and branches whose total membership at the same date was about 1 000 000 did not provide dental benefit The third

valuation of societies had not yet been completed, but the result thus far did not show any reduction in the amount allocated for the provision of dental benefit

In reply to Mr Rhys Davies, on November 6th, Mr Greenwood said that, under the regulations governing the provision of dental benefit, no distinction was made between employed and voluntary contributors Before varying the regulations in this respect, he required to be satisfied that there were sufficient reasons to justify the variation, and such reasons had not yet been put before him

Hospital Treatment of Pensioners

Mr F O Roberts on November 10th told Mr Stephen that after careful consideration, he had decided that Bellahouston Hospital could not justifiably be maintained beyond a date early in the New Year, so that the premises might be handed back to the Red Cross and the necessary reinstatements completed by the date of the expiry of the lease He had arranged with the committee of Erskine House for the use of that hospital for the type of case at present treated at Bellahouston The patients would be under the care of the same surgeon as heretofore He had also made arrangements with the Glasgow Royal Infirmary for the immediate admission of any case requiring urgent emergency treatment All out patients would be treated at the Glasgow Area Clinic

Mr Stephen asked if the right hon gentleman did not intend to have a hospital in Glasgow to serve the ex service men in the West of Scotland Mr Roberts said he did not know much about that locality What he had to do was to see that adequate treatment was provided for the men, and he was satisfied that the arrangements made with Erskine House as a general hospital would meet all requirements

Mr Roberts stated that the average number of disabled ex service officers and men (apart from cases of mental disease in mental hospitals) for whom the Ministry of Pensions is providing institutional treatment, whether for wounds or diseases, is, in round figures, 4 000

Opium

Mr Clynes, on November 10th told Mr Maude that considerable progress had been achieved with the consideration of the proposals made at the preliminary opium conference which recently opened in London, and it was hoped to submit a report in a few days

Mr Benn replying to Major Pole on November 10th, said that the Government of India had formulated a scheme for dealing with the preparation of opium in the Malwa States, and was discussing it with those States

Medical Records of Children Leaving School—Sir Charles Trevelyan told Mr Somerville Hastings, on November 6th, that in view of administrative difficulties involved and the interval which was likely to elapse between the age at which a child was last medically inspected in school and the age at which the first application for medical benefit was made, he did not feel justified in advising local education authorities to transfer to local insurance committees, when so requested copies of the medical records of children leaving school It had been impressed upon local education authorities that school medical records should be treated as strictly confidential He was unaware of any applications for these records Dr Vernon Davies asked if the records were available for certifying surgeons when they were examining the children No answer was returned

Tinfoil Cheese Wrappers—Replying to Sir C Cayzer on November 6th Mr Greenwood said that the statement of an analyst of a local authority quoted in a recent annual report of his department that the practice of wrapping cheeses in tinfoil was a potential danger to the health of the consumer was well founded He did not propose to publish any qualification

Poison Gas—Mr A Henderson told Mr Graham White, on November 10th that twenty seven States had both signed and ratified the Geneva Protocol of June 17th, 1925 undertaking to refrain from the use of asphyxiating or poison gases in war Nineteen other States had signed, or otherwise acceded to, this Protocol, but had not yet ratified it

Dublin Hospitals Sweepstake—Questions have been asked in the House of Commons concerning the Dublin hospitals sweepstake On November 10th Mr Pethick Lawrence informed Sir W Davison that his attention had not been called to the sums of money which were leaving this country for investment in the Irish Free State sweepstake

Notes in Brief

Mr Greenwood told Major Pole on November 5th, that fifty two county councils in England and Wales had incurred expenditure on the provision of milk and meals for expectant and nursing mothers and children under school age

The number of certified mental defectives in England and Wales on January 1st 1930 was 25,076 Of these, 1 591 were under guardians outside institutions The number of beds available in institutions was approximately 24 000

On October 1st last there were, approximately 1,895 000 persons in Scotland insured under the National Health Insurance Act

On November 10th Dr Addison told Mr Freeman that foot and mouth disease serum had no deleterious effect on the flesh of an inoculated animal subsequently slaughtered

In 1929 some 140,000 children were provided with spectacles under arrangements made by education authorities in England and Wales All local education authorities had the service of an experienced oculist, except the authority for the Isles of Scilly

Mr Roberts informed Major Cohen, on November 11th that in the nine years, up to September 30th last since the limit was enacted some 1 400 cases of late claim had been awarded pecuniary compensation by way of pension or otherwise, and about 500 cases surgical treatment had been provided

Universities and Colleges.

UNIVERSITY OF LONDON

Mr G E Vlvandre has been recognized as a teacher of radiology at the London Hospital Medical College, and Dr I W Disney as teacher of dental surgery at St Mary's Hospital Medical School

The following appointed and recognized teachers have been assigned to the Faculties indicated *Medicine* Dr A E Boycott (professor of experimental pathology, Cancer Hospital), Mr H J Gray (teacher of surgery, Hospital for Sick Children), and Dr D V Nabarro (teacher of bacteriology Hospital for Children) *Medicine and Science* Dr C R Harington (reader in pathological chemistry, University College Hospital Medical School)

It has been decided that recognition of the Cancer Hospital as a school of the University shall be continued until October 1st, 1931

A course of five lectures on Diseases of bacteria' will be given by Mr F W Twort, superintendent of the Brown Animal Sanitary Institution, in the theatre of the Royal College of Surgeons of England Lincoln's Inn Fields, W C , on December 1st 3rd, 5th, 8th, and 10th, at 4 p m Admission is free, without ticket

NATIONAL UNIVERSITY OF IRELAND

University College, Dublin

The following candidates have been approved at the examinations indicated

Third M B—*Part I* *D K O Donovan *J K Feeney †J L O Murphy *R Hayes †Irene A Foster †T J Fenton †J Reidy †M J Murphy †F Fleming †M P Gorman †J Duffy †J Fahy J J Dawson D Deasy J J Deasy D C McCarthy J P McCormack C A McDonnell J McSorley J J O Donnell T D Phelan, J Russell P G Ryan D F Savage M J Sheehan J Walsh *Part II* *T A Brady †J J Sheehan †T Crowley †P J O Doherty †J Phelan J Diver J Duddy Joan J Kennedy J McDonnell P W Rattery J J Sheehan

* First-class honours † Second class honours

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

A quarterly meeting of the Royal College of Physicians of Edinburgh was held on November 4th, when the President Sir Norman Walker, was in the chair

Drs Henry Leonard Wallace (Edinburgh) and William Brown O B E (Aberdeen), were introduced and took their seats as Fellows of the College

Drs Emile Macbeth Watson (Ontario), Wm Archibald Mein (Bournemouth) Agnes Rose Macgregor (Edinburgh) and James Davidson (Edinburgh) were elected Fellows of the College

The Hill Pattison-Struthers bursary in anatomy and physiology was awarded to Maurice Goldfarb, and the Hill Pattison Struthers bursary in clinical medicine to Robert Leitch Allan

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At the annual meeting of the Royal Faculty of Physicians & Surgeons of Glasgow, held on November 3rd, the following office were elected President Dr John P Fergus, visitor Mr I Barclay Ness, honorary treasurer, Mr J H MacDonald, honorary librarian, Dr L H L Oliphant

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At the monthly meeting of the President and Fellows, held on November 7th the following were duly admitted to the Fellowship of the College John Lait, Edward Keohan, Frederick MacSorley

The following were admitted as Members Thomas Craw Boyd James Michael O Donovan

The Licence in Midwifery was conferred upon A K Shem

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have been approved in the subjects indicated

Surgery—C L Ferguson H R Fosbery A R O Lahiffe S Lobb J M L Love J H W Lyle F O Parsons L C H Sykes P Wade

Medicine—R F T Finn B C Ghose C R Graham M Halpin T C Keble R D Newton C G Nicol G S Rozario C I Scott

Forensic Medicine—F J Jones R D Newton

Midwifery—H Glynn C R Graham J Inger W A Neil H I Newman

The diploma of the Society has been granted to Messrs M Abbas R F T Finn, B C Ghose H Glynn, C R Graham M Halpin T C Keble, J M L Love, H I Newman, R D Newton C G Nicol, C P Seeley

Medical News.

THE Nobel prize in medicine for 1930 has been awarded to Professor Karl Landsteiner of Vienna who since 1922 has been engaged at the Rockefeller Institute, New York, in the study of blood groups

THE annual dinner of the Old Epsomian Club will be held at the Hotel Great Central Marylebone Road, on Thursday, December 11th, at 7 30 o'clock

THE annual dinner of the Chelsea Clinical Society was held at the Rembrandt Rooms on October 28th under the chairmanship of Dr P J McCann The attendance was excellent 96 members and guests being present the latter including Lord Riddell, Sir Thomas Horder and the presidents of five hundred medical societies The first dinner meeting of the session will be held at the same place on Tuesday November 18th, when Dr Anthony Feiling will open a discussion on the treatment of headache All communications should be addressed to Mr A. Rugg Gunn, F R C S , 49, Harley Street W 1

A MEETING of the Medico-Legal Society will be held at 11, Chandos Street, W 1 on Thursday November 27th at 8 30 p m Dr F C Martley will read a paper on the importance of blood grouping tests in paternity cases a discussion will follow

AT the meeting of the Royal Microscopical Society to be held in the Hastings Hall B M A House Tavistock Square W C , on Wednesday, November 19th, at 5 30 p m the following papers will be read and discussed Mr R J Bracey, 'A universal tube length and cover glass correcting lens system for use with microscope object glasses Dr W E Cooke and Mr C F Hill "Microscopical studies in pernicious anaemia—I, The haemoglobiniferous cells

THE second meeting of the session of the British Institute of Radiology will be held at the Institute on November 20th, at 8 30 p m Dr G Simon will read a statement on the use of diathermy in pneumonia and Dr A Müller will describe an *x* ray generator with a rotating water-cooled target On the afternoon of the following day the radiological department of Charing Cross Hospital will be open to inspection by provincial medical members, and later there will be an informal discussion at the institute on the movements of the intestinal tract, which will be illustrated by a cinematograph film

A NEW course of post graduate lectures at the City of London Maternity Hospital City Road E C , will commence on November 20th, at 5 p m , when Dr J A Willett will discuss the importance of ante natal care The lectures will be continued on succeeding Thursdays at the same hour till February 19th 1931, with the exception of December 25th and January 1st

THE Fellowship of Medicine announces that in connexion with the M R C P examination lectures will be given at the Medical Society of London 11 Chandos Street Cavendish Square at 8 30 p m on Tuesday November 18th, by Dr T Izod Bennett on the conception of nephrosis, and on Friday, November 21st by Dr W J Adie on diseases of the nervous system Tickets are obtainable from the Fellowship or at the lecture hall A free lecture will be given at the same place on Monday, November 17th, at 4 p m , by Mr L C Rivett on recent advances in gynaecology and obstetrics The following free demonstrations will be given at the Golden Square Throat Hospital on November 17th at 2 p m by Mr F C Ormerod at King's College Hospital Denmark Hill, on November 19th at 2 p m by Dr M Critchley (neurology) and at the Royal Northern Hospital Holloway Road, on November 19th at 6 p m on gonorrhoea in the female, by Dr Violet Russell (for women graduates only) A special course will begin on November 17th at the City of London Hospital, Victoria Park continuing for two weeks and occupying the whole of each day with demonstrations and lectures on diseases of the heart and lungs At the West End Hospital for Nervous Diseases Welbeck Street there will be a daily course at 5 p m for four weeks from November 17th The subjects of the remaining courses in 1930 are proctology November 24th to 29th dermatology December 1st to 13 h and diseases of infants from December 1st to 13th The 1931 list of special courses is now ready and may be obtained on application to the secretary of the Fellowship 1 Wimpole Street London W 1.

THE list of medical mayors elected on November 10th include Dr Arthur Hawkyard as Lord Mayor of Leeds, Dr W S S oble as Mayor of Oxford, and Dr R F Bury re-elected Mayor of Leamington

THE National Homecroft Association, which has as one of its aims the carrying into practical effect of the teachings of the late Dr George Vivian Poore, author of *Rural Hygiene*, is holding a meeting on Thursday next November 20th, at 3 p m in the Church House Dean's Yard Westminster Dr F G Crookshank will take the chair and Professor J W Scott will outline the steps taken to realize the project of a memorial to Dr Poore So far more than £250 has been subscribed towards the proposed memorial and a further sum of £200 has been promised Inquiries and subscriptions may be addressed to Professor Scott at the offices of the association, 38 Charles Street Cardiff

THE Woodside Nerve Hospital at Muswell Hill of which we published some particulars in our issue of November 1st (p 741) was opened by Princess Helena Victoria on November 8th In declaring the hospital open the Princess expressed her opinion that such an institution would meet a real want and would amply justify the care and expenditure incurred Lord Blanesburgh chairman and treasurer, said that the hospital was for the benefit of cultured people of slender means It was hoped that with the assistance of the larger fees of some patients it would be possible to treat a number of people without resources Sir James Purves Stewart said that the hospital would not be run as a business proposition but as a contributory benevolent institution

AT a meeting of the National Baby Week Council, held on November 12th, a discussion on the necessity for routine medical inspection of the child from the age of 1 to 5 years was opened by Dr Eric Pritchard, chairman of the executive committee who was followed by the joint honorary secretaries of the council Dr D H Geffen medical officer of health for Enfield, and Mrs Sophia Friel M D The prizes awarded in the council's essay competition for domestic science pupils were presented

ST BARTHOLOMEW'S HOSPITAL contributed to the Lord Mayor's Show on November 10th a pageant emphasizing the services rendered by the hospital throughout the world Celebrated teachers and students of the past were also portrayed in the procession and there were references to the part played by St Bartholomew's in past centuries, and also to the claims of its extension fund

THE Minister of Health has issued a circular (No 1153) describing the form in which county borough councils and authorities of areas with a population over 20 000 may submit quinquennial statements of their proposals for dealing with the housing conditions in their areas and for providing new housing accommodation as required by Section 25 of the Housing Act 1930 In the preparation of their statements which must be submitted to the Minister before the end of December next councils are reminded that their medical officers of health have been advised (Circular 1119) to include special housing information in their annual reports for the current year (The contents of this circular were referred to in the *British Medical Journal* of June 28th p 1194.) The dominant figure of the statement will be the estimated number of houses which councils are able to provide to meet the requirements of their districts whether they are to be used as additional houses or for rehousing purposes In considering the need for new accommodation special regard must be given to the waiting lists of applicants for houses which will probably include persons residing in houses whose demolition is contemplated by the Act

DR C P BLACKER, M C has been appointed general secretary of the Eugenics Society as from November 1st, 1930

DR EMILE F HOLMAN professor of surgery at Stanford University has been awarded the Samuel D Gross prize for his research on abnormal arterio-venous communication

AT the recent opening of the Banting Research Institute the Doctorate of Laws of the University of Toronto was conferred on Dr Thomas S Cullen, professor of clinical gynaecology at Johns Hopkins, in recognition of his work on cancer

THE issue of the *Wiener medizinische Wochenschrift* for November 1st is dedicated to the Vienna paediatrist Professor Hochsinger on the occasion of his seventieth birthday and contains articles dealing exclusively with diseases of children

ON the occasion of its tenth annual meeting the German Society for Diseases of the Digestive System and Metabolism has founded a Boas prize of the value of 1 000 marks The subject is the bacterial and non bacterial origin of diseases of the pancreas Candidates should send in their essays by April 1st 1931 to the general secretary Professor P von den Velden 30 Bambuga Strasse Berlin from whom further information can be obtained.

A MEMORIAL tablet has been affixed to the house where Paul Ehrlich was born at Strehlen in Silesia

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W C 1***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House Tavistock Square, W C 1, on receipt of proofs

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863* and *9864* (internal exchange, four lines)

The ***TELEGRAPHIC ADDRESSES*** are

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc), *Articulate Westcent London*

MEDICAL SECRETARY *Medisecra Westcent, London*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus Dublin* telephone 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams *Associate, Edinburgh* telephone 24361 Edinburgh)

QUERIES AND ANSWERS

Infra red Rays

DR H E GIBSON (South Godstone) writes I should be glad if some expert in physics would inform me whether infra red rays penetrate ordinary glass, or are non penetrating, like ultra violet rays

*** Ordinary glass—window glass—is fairly transparent to all the infra red rays which we receive from the sun, after these have been filtered by the gases of the atmosphere Such glass is however opaque to the much longer waves received from low temperature sources, such as a gas burner or domestic fire The use of a magnifying glass as a "burning glass" when held in sunlight, and the action of a common glass fire screen, exemplify both effects

Angioneurotic Oedema

DR P G SHEPPARD (Liverpool) writes In reply to the inquiry of H C B in the *Journal* of November 8th (p 806), I would suggest strict attention to diet and the employment of saline laxatives and antacids, with sodium benzoate in 5 to 20 grain doses three times a day As a purgative the ordinary antacid magnesia may be given and a gastro intestinal antiseptic, such as salol If these fail I would recommend a dose of salvarsan, thyroid extract in daily half grain doses has proved useful

Cyanosis with Collapse

DR L R LEMPRIÈRE (medical officer to Haileybury College) writes Can any reader throw light on the following incident?

On October 28th a boy, aged 14 came into the school hospital about 12 30 p m complaining of feeling very faint and ill In spite of his faintness he was not pale, but bluish, his pulse was small and quick (100) He was given some sp ammon aromat and lay down half an hour later he was no better, and was carried up to bed Within another half hour I went into the ward, and found him lying on his side with his head into the pillow, the face neck, and hands having a deep blue black colour He was breathing very slowly and lightly, was cold but not clammy and his pulse was almost imperceptible, but he was not unconscious for he answered questions He was immediately given an injection of pituitrin, to which his pulse soon responded, and a little later camphor and ether, with some brandy Twenty minutes later he said he felt much better, but had a bad headache The blue colour remained almost the same, and he was given frequent inhalations of oxygen Between 2 30 and 6 p m he vomited half a dozen times, but his colour steadily improved, though he remained dusky hued until the next day by which time he seemed perfectly well He was discharged fit on November 2nd, having had no further symptoms He had been perfectly well until he began to feel faint while at a drawing lesson at noon Between 10 a m and noon he had been at a science class and had got some aniline dye on his lips and a drop in his mouth, but he had immediately washed his lips and mouth thoroughly Also he had seen the school dentist who had put a fibre dressing containing arsenic into a lateral incisor This I removed about 3 p m , the dressing was a very small one in the root and the dentist estimates the amount of arsenic as less than 1/32 grain of arsenious oxide Could the signs and symptoms related be due to this small amount of arsenic? The boy was seen by another doctor between 4 30 and 5 p m , when he was much better and out of danger, he then looked like a case of patent foramen ovale The heart was frequently examined, but was quite normal, there was no enlargement of either side, and no history of previous heart trouble or fainting

Income Tax

Income from Additional Appointments

"J M " is in general practice and holds an appointment as sub-vaccinator In April, 1930, he was appointed visiting medical officer to a children's home and in October medical officer for an infant welfare centre How should income from these sources for the year 1930-31 be assessed? Also, how are the periodical payments of vaccination bonus (1s per case) usually dealt with for income tax purposes?

*** In strict law the income from such appointments is assessable separately under Schedule E, and on that basis the first year's earnings should be assessed on the basis of the amount for the actual financial year, and thereafter on the basis of the preceding year Frequently, however, such income, where relatively small, is not, in fact, separately assessed, but is allowed to be included in the general receipts Presumably that course, however, involves some small loss to the Revenue seeing that, if the appointment be held for a number of years, one year's income therefrom would not be reflected in the practice statements So far as the bonuses on vaccination work are concerned, the rule appears to be to regard them as receipts of the year in which the payments are made, and to bring them into the assessment figures accordingly on the previous year's basis

Replacement of Car

"G O C" bought a car in May, 1926, for £200—wear and tear allowance was never claimed on that car In June, 1930, he sold the car for £70 and bought a new car for £410 On October 1st he left his former practice and started professional work elsewhere

*** It is a pity that the wear and tear allowance was not claimed, as we have pointed out before it always pays to do so As it is, "G O C" seems to have lost the chance of obtaining any relief for the loss on the old car, because he cannot treat that as an expense of carrying on his present practice We can only advise him to claim depreciation on the new car for 1931-32 and future years It would be possible for him to claim an adjustment of the tax assessed for the last period of the old practice and to charge the renewal cost to that account, but that would involve interference with the liabilities of his former partners, which 'G O C will presumably wish to avoid

LETTERS, NOTES, ETC

Congenital Absence of the Bile Duct

DR S WARD (Birmingham) who contributed a note on a case of congenital absence of the bile duct, which was published in the *Journal* of July 6th, 1929 (p 36), has now sent some further details The patient has recently given birth to another child, a girl, who is at present alive and healthy Dr Ward writes — The interesting points to me in this case are apparently the 'fault" lies with her second husband, the condition has only occurred in male children in the family, the absence of jaundice at birth, and the incidence of two cases in one family, the woman's three children by her first husband being all alive and well

Radiologist and Radiographer

'CAPE PROVINCE writes We require an accurate definition of the word "radiologist,' at present used quite loosely in South Africa For confirmation of this one has only to refer to the minutes of the recent Federal Council meeting at Durban The first essential of a radiologist is a medical qualification Those bodies in Great Britain which confer qualifications in radiology specify this, adding that the qualification must be an approved one The term "radiographer' might properly be applied to a layman doing the work, though not expected to interpret results

An Improvised Bed Desk

"A A G D writes A very handy appliance for reading in bed is an ironing board which stands on its own legs, with a board 1 yard long projecting It only requires to have a board 15 in by 24 in screwed on to it, and can then be used as a tea table or writing table A reading board can also be added to it It stands firm, will not tip over, and can be painted any colour The total cost is about 10s 6d

Vacancies

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 56, 57 58, 59 60, 61, 65 and 66 of our advertisement columns, and advertisements as to partnerships, assistantships and locumtenencies at pages 62 63 and 64

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 223

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine.

433. Dyspepsia in Pulmonary Tuberculosis

E SKOUGE (*Norsk Mag f Laegevid*, September 1930 p 945) examined the gastric secretion in 102 cases of pulmonary tuberculosis by Ewald's test breakfast with the following results In the early stage it was frequent to find hyper acidity and cases with a tendency to this condition while in the advanced stage there was a pronounced incidence of subacidity and anacidity In 23 patients who showed anacidity after Ewald's test breakfast a control examination by histamine was performed with the result that 17 of the 23 cases proved to be examples of false achylia In the remaining 6 cases alcoholism syphilis or cancer could be regarded as responsible for the achylia Skouge therefore comes to the conclusion that the uncomplicated gastritis of *patients with pulmonary tuberculosis* is not connected with deep changes in the gastric mucosa and that its development is so slow that generalized gastritis hardly ever ensues even though the tuberculosis has been in existence for many years *Symptoms of dyspepsia are most frequent in the early stage, and in advanced tuberculosis of the exudative form as is shown by the fact that 71 per cent of patients in* the former stage and 89 per cent of those in the latter complained of dyspepsia In cases of advanced phthisis mainly of a fibroid character, 50 per cent showed dyspeptic symptoms

439 Etiology of Pernicious Anaemia.

J BLAIR (*Med Journ and Record*, September 3rd 1930 p 209) believes that pyelitis will probably be found by careful observers in all cases of pernicious anaemia He discusses the infectious origin of this disease and the relation of pyelitis to achlorhydria and pernicious anaemia The blood changes, the fever and the achlorhydria in pernicious anaemia, and the incidence of achlorhydria in other affections, as gastric carcinoma, are discussed, and it is shown that many clinical symptoms of pernicious anaemia and pyelitis show a marked similarity Blair draws the following conclusions from this study The actual anaemia of pernicious anaemia is not due to erythrocyte haemolysis or excessive destruction in the vascular system, but to a deficient formation of erythrocytes, which deficiency is caused by a lack of sufficient stroma material for their formation *In pyelitis* granular leucocytes are constantly lost from the body and its occurrence in pernicious anaemia constitutes an insistent demand for granular leucopoiesis. Certain common relations exist between erythrocytes and granular leucocytes their formation in the same location (bone marrow) in the adult their decreased formation in the relapses of pernicious anaemia and their simultaneous response to liver therapy The excessive production of leucocytes over a long period probably deprives the body of the substance (the specific 'x factor of liver) necessary to both granular leucocyte and erythrocyte formation and is thus responsible for both the anaemia and the leucopenia The achlorhydria in pernicious anaemia is probably the end result of a chronic mild stimulation of the gastric secretion associated with a mild chronic infection (pyelitis), and producing an exhaustion of the secreting mechanism of the stomach from overuse, coupled with the loss from the stomach tissues of the specific 'x' factor normally present in these tissues Hence the presence of pyelitis in pernicious anaemia gives an adequate explanation of the fever loss of weight tendency to remission and relapse and other symptoms *The prevention* of pernicious anaemia is therefore the prevention of focal infection and consequent urinary tract infection the detection and cure of focal and urinary tract infection already established and the preventive or palliative administration of the specific substance found abundantly in the liver

440 Geographical Distribution of Rheumatic Fever

SINCE study of geographical distribution has greatly aided the unravelling of the causes of disease J T CLARKE (*Journ Trop Med and Hyg* September 1st 1930 p 249) believes *that if rheumatic fever* can be proved to be confined to extra tropical countries, the search for its cause will have been greatly narrowed The disease has frequently been described as ubiquitous an opinion which Clarke strenuously combats maintaining that it is unknown among the inhabitants of the Tropics For the purposes of this study accurate definitions of the Tropics and rheumatic fever are given By the former is meant that region which lies between the latitude 23 28 north and south thus only parts of India China Egypt and Arabia are described as tropical Rheumatic fever is defined as a specific febrile disease which has a particular incidence on the heart and which frequently presents as its prominent features polyarthritis chorea and subcutaneous nodes The essential typical lesion is the Aschoff body these cells are *the precursors of the fibrous scar tissue which in the heart* produces mitral stenosis The presence or absence of mitral stenosis has a great bearing on the question of the presence or absence of rheumatic fever During thirty three years of *medical work in the Tropics during which time about 150 000* patients were seen Clarke did not find a single case of rheumatic fever mitral stenosis or chorea nor in many post mortem examinations was a valve found suggestive of the scarred valve of a rheumatic heart It is pointed out that certain diseases occurring in the Tropics such as undulant and relapsing fever, have *rheumatic like affections anaemia and* cardiac murmurs (not mitral stenosis) as complications and sequels A general review of the literature bearing on the geographical distribution of rheumatic fever and its racial incidence is given Clarke strongly maintains that the disease does not arise in the Tropics and that any case found in such countries has originated elsewhere He adds that If this is true, every theory as to its causation must be reconsidered, and new lines of research instituted There would appear to be some factor, common in one part of the world and rare in others, which investigation should eventually bring to light

441 Indications for Blood Transfusion.

J F LANDON (*Amer Journ Med Sci*, October 1930 p 514) records his observations on 100 cases of various acute infectious diseases treated by blood transfusion at the Willard Parker Hospital New York, during a period of three and a half years He concludes that such transfusions are contraindicated in diphtheria when it is complicated by myocarditis, and in laryngeal diphtheria, especially when broncho-pneumonia is present This form of treatment is however, a valuable adjuvant in the pre- and post operative treatment of *mastoiditis sinus thrombosis* and empyema particularly when these conditions complicate scarlet fever *or measles It is also of value in the treatment of broncho-pneumonia complicating measles and whooping cough* It is strongly indicated as a general tonic in protracted cases accompanied by anaemia and malnutrition.

Surgery.

442. Non union of Fractures.

DISCUSSING certain principles in the treatment of non united *fractures* F H ALBEE (*Surg Gynecol and Obstet* September 1930 p 289) distinguishes four overlapping stages in the process of union—namely preliminary fibrous union (granulation tissue) which is identical with the union of soft tissue formation of soft callus development of hard callus and the adaptive reconstruction of the callus The complexity of the process can be fully understood only after considering the functions of bone and their interrelation with other bodily functions The metabolic function of bone, its importance in storing calcium the presence of an enzyme (phosphatase) which is secreted by the osteoblasts and the dependence of bone growth on the activities of other organs such as the thymus sex glands thyroid and pituitary glands are dealt with Non union may result from various factors including infection and the disorganization of the soft callus by rough manipulation the causes may be grouped in o tho e concerned with the formation of granulation tissue and those concerned with the ossification of that tissue the end re ul varying with the fate of the granulation tissue While measures directed to the improvement of the general health will aid bones to unite Albee maintains that an open operation is the only way to treat non union bone grafting being the method advocated The entire process of union and the survival of the graft depend on the es ablishment of vascular connexions between the graft and the host fragments and this requires accuracy of appo ition The use of autom tic power-driven tools which can be adjusted to cut with exactness to h the graft bed and the graft is advised The step-up operation of Senn and mechanical fixation and o her methods are criticized Albee describes his technique of bone grafting

with inlays, sliding, and double wedge end grafts If infection is present, this must be eradicated before the grafting is performed Likewise, extensive scar tissue should be removed and replaced by an ample pedicle graft, usually obtained from the other limb, the bone grafting should not be undertaken for at least one month after this The post operative treatment, which must include much physiotherapy, is outlined The ultimate results in 754 cases of non union were good in 671 (89 per cent) and poor in 83 (11 per cent)

443 Hirschsprung's Disease

R B WADE (*Journ College of Surg of Australasia*, July, 1930, p 3) defines Hirschsprung's disease as a condition in which an enlarged and dilated colon is associated with constipation and a gross degree of abdominal enlargement It may be present at birth or may occur shortly afterwards, and is thought to be due to some neuro muscular incoordination In mild cases constipation is the most marked symptom Apart from anaemia and slight abdominal distension the child may be moderately well, but in more severe cases constipation may be found, no natural bowel action occurring for weeks or even months In these cases there may be attacks of acute distension and vomiting, with convulsions, and death may ensue during one of them Peristaltic waves are most evident in patients who are much emaciated, in these cases the dilated loops of the pelvic colon appear to fill the whole abdominal cavity Daily purgatives and enemata will relieve the symptoms but will not cure the constipation Of the various operative measures which have been used that of sympathetic lumbar rami section has given good results Thirteen cases are reported by Wade, in nearly every instance the constipation was relieved, a normal action being established by the time the child was convalescent Abdominal distension and dilatation of the colon decreased slowly, and the children improved in general health

444 Primary Carcinoma of the Lungs and Bronchi

E V GOLTZ (*Minnesota Med*, September, 1930, p 605) has seen an increasing number of these cases in recent years, as also have many authorities in Europe and America, it is greater than the total increase of all forms of cancer, and is not entirely accounted for by increased longevity, alterations in pathological classification, improved diagnosis, or more general hospital attendance The percentage of primary lung cancer, compared with the total of all cancers, has increased three or four times This suggests that some chronic irritative factors have been becoming more common recently Influenza is probably the chief bacterial factor, a definite increase of lung cancer followed the pandemic of 1918–19, and chronic bronchitis, fibroid pneumonia, and syphilis may predispose also Chemical and mechanical forms of irritation may be supplied by smoke, fumes, road dust, and possibly tarred roads, half a million tons of tar are used annually on American roads, and pulmonary cancer is very rare in Hong Kong and Singapore, where roads are not tarred Lung cancer is very prevalent among Saxon miners, and it is said that 50 per cent of old miners have died from this disease, while no cases occurred among the rest of the population, arsenic contamination in the cobalt and bismuth mines is supposed to be the cause The injuries due to gas inhalation in the war is also cited as a possible cause of the increase The pathology of these tumours is obscure. Most authorities believe that the majority of tumours arise in the bronchial mucosa Metastases may appear early in the liver, kidney, and suprarenal glands, or the primary tumour may invade the lung, even displacing an entire lobe Partial or complete bronchial obstruction ensues, and broncho pneumonia is usually the immediate cause of death The majority of cases occur between the ages of 45 and 65, and the average duration is seven months Cases in men are three times as numerous as in women Sudden haemorrhage may be the initial symptom, or the case may simulate acute pleurisy or pneumonia, the onset may also be gradual, with cough, pain, and dyspnoea The cancer may be entirely latent, manifesting itself by metastases in the brain, bones, or viscera The physical signs are always confusing, they may be absent in early cases, or may suggest broncho pneumonia, atelectasis, bronchiectasis, lung abscess, or pleurisy Cough is the most frequent symptom, but it may be absent, or atypical Paroxysmal cough with intense pain and dyspnoea, accompanied by scanty, sometimes blood tinged mucus, is very suggestive of bronchial cancer, especially when occurring in elderly patients Pain is usually felt in the chest, but may be referred to the neck, back, abdomen, or limbs, it arises from nerve pressure, pleural irritation, pericarditis, or involvement of the spinal cord or nerve plexus Wasting is found in 50 per cent of cases, and may begin early Cyanosis and venous dilatation due to mediastinal pressure, laryngeal paralysis, and dysphagia may occur, and occasionally signs of pulmonary osteo arthropathy are seen Since the tumour usually occurs in the larger bronchi, application of the local cautery, with radium possibly, offers the best hope At least twenty eight cases of lobectomy and other surgical interventions have been recorded, one patient lived for five and another for three years after the operation Deep x ray therapy sometimes relieves the pain, but fails to arrest the progress of the tumour

Therapeutics.

445 Gold Treatment of Advanced Tuberculosis

J W KIME (*Med Journ and Record*, September 17th, 1930, p 274) records his experience with gold in the treatment of pulmonary tuberculosis Using one of the standard preparations, he commenced with advanced and hopeless cases, discovering that within a few days after the first dose the sputum, which had previously shown a few scattered extracellular bacilli, became loaded with enormously increased numbers, many of them lying within the polymorphonuclear cells The bacilli had a decided tendency to clumping in circular form of corresponding size to the leucocytes, but with no cell structure visible, as if the bacilli had been gathered up by the leucocytes which were eventually destroyed In some cases the fields were densely crowded with masses of the bacilli, apparently as the result of an intense phagocytosis Deep intramuscular injections into the deltoid were given, these resulted in severe pain for about a minute, but there was no soreness or local reaction The solution is self sterilizing, but the steel needles quickly corrode and become plugged Kime remarks that there is generally a slight temperature reaction within a day or two Examinations of the sputum should be made daily, and though the characteristic results may not be found every day they generally occur within a week of the first or second dose He considers that a curative course should continue for six months to one year, after such administration he has seen the bacilli disappear by disintegration within the cells, the patients remaining well three years later The process of cure can be microscopically followed, the cell activity or bacillary impairment resulting in an intense phagocytic activity, and the leucocytes engulfing the bacilli in large numbers That gold so used has a specific selective action upon tuberculous tissue was noted in a few open cases, a tuberculous wound in the neck healing very rapidly although the patient was dying

446 Barium Chloride in Heart-block

A E PARSONNET and A S HYMAN (*Amer Journ Med Sci*, September, 1930, p 356) record their experience of treatment with barium chloride in eight cases (seven men and one woman, whose ages were between 51 and 68) of auricular and ventricular dissociation exhibiting the Stokes Adams syndrome The doses ranged from 0 16 to 0 4 gram per day, and the total amounts given from 9 6 to 40 32 grams The treatment was continued in one case for as long as 126 days, and in no case lasted less than 40 days, but in no patient was any effect, either good or bad, noted, and no confirmation was obtained of the favourable results reported by previous investigators of barium chloride given by mouth, even in larger doses than those previously reported Great care was taken to procure a chemically pure salt, and tablets containing 0 04 gram were obtained which were readily soluble in water and conformed to the standard fragility tests Two deaths occurred, but neither of these were in a period less than three months after the administration of the barium The authors consider that this series of eight cases in this by no means common condition is sufficient to throw doubt on the efficacy of barium treatment in the Stokes Adams syndrome of complete heart block

447 Treatment of Malignant Diphtheria

IT has been demonstrated in animal experiments that antitoxin is only effective in counteracting a lethal dose of diphtheria toxin if not more than six to ten hours are allowed to elapse before it is injected, after this interval it has no effect, no matter how large the dose K KUNDRATITZ (*Med Klinik*, August 29th, 1930, p 1289) suggests that in these cases a large proportion of the toxin becomes "fixed" in important tissues such as the heart, and is thus out of reach of the antitoxin, which can only neutralize circulating toxin Similar conditions probably prevail in malignant cases of diphtheria in human subjects, though whether the prevalence of this type in some epidemics is due to increased virulence or to increased susceptibility is still uncertain By using theophyllin (or euphyllin) Kundratitz has attempted to increase the permeability of the tissue cells in order thereby to liberate some of the "fixed" toxin, and to facilitate the

access of antitoxin to the cells The guinea pigs used for the tests were divided into groups according to the number of hours which were allowed to elapse between the injection of toxin and the onset of treatment, either with antitoxin alone or with a combination of antitoxin and theophyllin theophyllin sodium acetate in doses of 0 0001 gram per gram of body weight was used in a 3 per cent aqueous solution The results showed a lower mortality among those animals which were treated with a combination of antitoxin and theophyllin than among those which received antitoxin only A number of cases of malignant diphtheria admitted to the Mautner Markhof Children s Hospital were then treated along similar lines Antitoxin was given in the following doses 10 000 to 20 000 units intravenously on admission, 10,000 to 20,000 units intramuscularly one hour later, 10 000 units seven and a half hours and nineteen and a half hours after admission, and if necessary twenty four hours later Subcutaneous injections of ½ to 1 c cm euphyllin (according to the age of the child) were given half an hour before the second and third injections of antitoxin and with the fourth and fifth injections Drugs to improve the circulation, and plenty of fluids because of the diuresis induced by the theophyllin were also administered Kundratitz was unable to draw definite conclusions regarding the value of this treatment, partly because of the difficulty of clearly differentiating the malignant type, and partly because there were fewer malignant cases in the period under observation (1929–30) than in the preceding years He found, however, that the proportion of deaths to recoveries in the euphyllin cases was 8 to 6, and in those treated without euphyllin 13 to 6 patients dying within twenty four hours of admission being excluded, his general impression of the method was favourable

Dermatology.

448 Dermatitis due to Chronic Irritation

DURING the past two or three years C DU BOIS (*Ann de Derm et de Syph* August, 1930, p 829) has noted exclusively in females, cases of ringed dermatitis, which he suspected were due to modern artificial ornaments composed of chemical combinations A case is reported which appears to prove the truth of this supposition The patient had worn for the first time a bracelet of artificial yellow crystals, composed of galalith (a formalin hardened casein preparation) and other substances, for four hours one evening The next day clearly marked red streaks were noted on the arm these were slightly pruriginous and were attributed to pressure of the bracelet However the redness and pruritus increased the inflamed bands became much raised and covered with miliary vesicles and the forearm began to swell On the fifth day the bands (each corresponding with the base of a segment of the bracelet) surrounded the arm with perfect regularity, there being apparently normal skin between their well defined edges Despite treatment the dermatitis became generalized as an intense erythema with swelling of the face and of the mucosae of all the natural orifices and an intolerable pruritus Then the eruption became clearly eczematous, it was accompanied by oozing behind the ears and in the articular folds, and interdigital and palmar dyshidrosis with enormous vesicles After three weeks treatment with emollient baths and desensitization by a hyposulphite preparation the condition ameliorated the skin at the sites of the primary bands alone remaining pigmented A furunculosis of nearly all the articular folds then supervened The crystals contained synthetic resins with a urea and formaldehyde base The patient when a child, had suffered from a general eczema following the application of dilute solutions of formalin for mosquito bites Cases are also cited by Du Bois of glossitis and inflammation of the lips caused by the use of dentures and cigarette holders composed of similar resins He contrasts the condition described, which he terms eczematiform dermatitis, with that of true or constitutional eczema the sensitization in the first case to the particular substance is not equivalent to that in the case of constitutional eczema, though the cutaneous reactions may be identical in both

449 The Treatment of Lupus Vulgaris.

A REYN (*Ugeskrift for Laeger* July 31st 1930, p 742) reviews the present position of the treatment of lupus throughout the world The magnitude of the problem in connexion with the need for institutional treatment of patients suffering from lupus is made clear by the fact that in Germany alone there are between 60 000 and 70 000 such cases Finsen light treatment which before 1914 was practised in many parts of the world was neglected in the belligerent countries during and after the war but in the last few years has again gained ground in many places It is the treatment most commonly employed in Denmark, and is capable of effecting a cure in 90 per cent of cases if carried out properly In the ten year period 1914 to 1923 Reyn was responsible for the treatment of 957 patients, 735 of whom were cured, there remained 75 still under treatment, and 147 who did not complete it Only in eight cases was the treatment carried out strictly according to the instructions without a cure being effected X ray treatment, extensively practised in Germany, is held by Reyn to be indicated in a very limited number of cases as a supplementary measure it is very rare for it alone to effect a cure and this is achieved at the cost of x ray injuries the skin becoming atrophic and subject to injuries and infections which are slow to clear up The danger of x ray carcinoma is considerably greater for patients suffering from lupus than for others and abroad the incidence of lupus carcinoma has shown an appreciable rise since the treatment of lupus with the x rays was introduced More and more warnings are therefore coming from Germany on this score Since the introduction in 1908 of the treatment of lupus by diathermy no great extension of its application for this lesion has been observed and at the present time it is but little employed in Germany relapses are frequent and very difficult to treat Various improvements of the technique have been suggested, and most authorities now agree that it should be employed only as a means of dividing tissues with a view to excision, but in Reyn s opinion a simple surgical excision is much to be preferred He insists on the importance of general treatment and of regarding the cutaneous lesion as an outward manifestation of a deep-seated infection

450 Keratoderma Blennorrhagicum

F RONCHESE (*Urol and Cut Rev*, September, 1930 p 591), who records an illustrative case states that since Vidal s first description of keratoderma blennorrhagicum as a clinical entity in 1893 a relatively small number of cases have been reported There are only about 90 instances on record but probably some cases pass unrecognized being wrongly diagnosed as epidermophytosis or keratosis of a different etiology Ronchese s patient was a lad aged 18 who developed keratodermia while suffering from subacute gonorrhoeal urethritis prostatitis and arthritis The typical acute inflammatory symmetrical lesions were on the feet and hands raising and disintegrating the bed of the nails of the fingers and toes in the lumbar regions the lesions were conical like those of rupia The gonococcus was present in the urethral discharge and the complement fixation test for gonorrhoea was strongly positive

Obstetrics and Gynaecology

451 Labour in Elderly Primiparae.

T ESMANN (*Ugeskrift for Laeger*, August 21st 1930 p 795) finds that the problem of the elderly primipara is being solved in certain quarters, and particularly in Germany with increasing frequency by means of Caesarean section In his private hospital where primiparae aged 40 and over constituted less than 1 per cent of all the confinements 34 out of 75 confinements were in women aged 40 The corresponding number for women aged 41 was 15 and the figures for women aged 42, 43 44 45 and 46 were 11, 8 1 3 and 3 respectively In the case of 37 head presentations and 4 breech presentations, labour was completed spontaneously, and in 2 other cases of breech presentation threatened intrauterine asphyxia necessitated manipulative manœuvres for the completion of labour One of these 43 patients died from pulmonary embolism on the eighth day Among these 43 confinements there were 4 deaths among the infants, and in 30 cases forceps had to be used with 3 infantile deaths Altogether eight infants died Caesarean section was undertaken only in one case, the patient being a primipara aged 40 with a flat rachitic pelvis The infant was born at term and weighed 7 lb 5 oz In as many as 7 cases (9 3 per cent of the 75 cases) the placenta required manual extraction whereas the author had to undertake manual detachment of the placenta in only 0 79 per cent of a series of 6 30- confinements at all ages While the average weight of the infants spontaneously born was 7 lb 2 oz., that of the infants requiring forceps extraction was as great as 7 lb 11 oz., and it would therefore seem that the high proportion of confinements requiring forceps extraction depended to a certain extent on the weight of the infants Esmann concludes that labour in elderly primiparae presents pathological incidents so often that the e women should always seek hospital treatment but he also considers that his investigation does not support Hirsch who advocates the routine performance of Caesarean section in these cases Esmann admits however, that in at any rate two of his cases the lives of the infants could have been saved with certainty had Caesarean section been performed In 1916 Leopold Meyer of Denmark classified elderly primiparae as (1) those who only late in life are given a chance

to conceive, but who conceive easily, and (2) those who, in spite of every provision for conception in their youth, fail to conceive before they are elderly Meyer suggested that labour in the first group does not present greater difficulties than it does in primiparae of more tender years, whereas it is from the second group that the cases of protracted difficult confinements with faulty labour pains, rigidity of the cervix, and lack of elasticity of the maternal passage are drawn Esmann has checked this hypothesis in the light of his own material, finding records bearing on this point only in about a third of his cases, they fail to confirm Meyer's hypothesis

452 Streptococcal Puerperal Sepsis

Endeavouring to cultivate haemolytic streptococci from cervical smears, W A Daloe (*Amer Journ of Obstet and Gynecol*, August, 1930, p 174) found them present in 1 4 per cent of ante natal, 3 2 per cent of natal, and 9 8 per cent of post natal cultures Each group included four to five hundred cases, and the cultures were made respectively fourteen days before term, in the second stage of labour, and on the second to tenth day The observations extended over two years, and the proportion of cultures positive for *Streptococcus haemolyticus* was considerably higher from February to May, at the same time the puerperal morbidity rate was higher Of the total morbidity, 32 per cent was due to puerperal sepsis, and of these septic cases 52 per cent were due to *Streptococcus haemolyticus* Of 52 patients showing this organism in the post partum culture 32 had clinical signs of puerperal sepsis, but in 20 there was no evidence of infection The 32 patients, of whom 17 had temperatures of 102° or more for twenty-four hours, and were regarded as serious cases, recovered with one exception The small mortality is attributed in part to the fact that in severe and moderately severe cases 30 to 45 c cm of scarlet fever antitoxin was injected intravenously or intramuscularly.

453 Primary and Secondary Ovarian Cancer

M R Robinson (*Surg, Gynecol and Obstet*, September, 1930, p 321) reports cases of granulosa cell cancer, papillary adenocarcinoma, and secondary or metastatic cancer of the ovary, and expresses his belief that primary ovarian cancer arises from epithelial elements which constitute part of the fully formed sex gland and not from hypothetical embryonal rests (Cohnheim's theory), that tumours during their evolution present different phases of growth which do not need separate classification, that a close relation exists between growth and function, and that tumours may and do assume the function of the organ from which they spring The histogenetic source of granulosa cell cancer is the epithelium of the Graafian follicles, and the folliculoid, medullary, and solid forms of this neoplasm are not different cancer types, but different phases in one and the same tumour. The main points of difference between this and other types of ovarian carcinoma are the rotundity and uniformity of the epithelial cells during the early stages, the rarity of mitosis, and the absence of invasive and destructive propensities Primary ovarian cancer, particularly the granulosa, may augment the still active ovarian function, or revive it after it has been quiescent, this is manifested clinically by hyperactivation of the endometrium, resulting in increased normal menstruation, or in periodic uterine bleeding after the menopause Secondary cancer does not influence the ovarian function at first, but as the disease develops the function is progressively suppressed Histopathological differences account for this The primary type is derived from the ovarian generative elements and possesses the same hormone producing properties as the ovary, therefore, with increased hyperplasia of this tissue the hormonic index rises The epithelium in secondary cancer is of extra ovarian genesis, and therefore has no relation to ovarian function The blood should always be tested for increased or diminished hormone content in the differential diagnosis between primary and secondary ovarian neoplasms Malignant papillary tumours and papillary adenoma of the ovary arise from the surface epithelium of the ovary, the epithelium lining its cysticles, and the epithelium of cystic follicles The adjacent position of normal and malignant epithelium in papillary tumours indicates that the transition from a benign to a malignant state is a sudden one Also metastatic carcinoma is indicated when the surface epithelium is intact, and the tumour is not adherent to any adjacent organ or tissue, the primary focus should be sought Owing to the successive nature of primary ovarian cancer the opposite ovary and uterus must be removed in cases of apparently unilateral malignancy The granulosa cell cancer is the most benign, in papillary adenocarcinoma the prognosis is far less favourable Metastatic ovarian cancer is the most malignant, the reactions in the ovaries are very pronounced, and removal of these organs does not eradicate the root of the disease.

Pathology.

454 Pathogenesis of Rickets

C E Bloch and F Faber (*Acta Paediatrica*, August 18th, 1930, p 10) present a study of seventy one cases of clinical rickets in children from 2 months to 2 years old These cases fall into groups according to lowness of the serum calcium, the serum phosphorus, or of both It was found that tetany occurred if the serum calcium was low, the threshold being at 8 3 mg per cent, except in the case of very debilitated children or those up to 3 months old, where tetany did not occur even with a lower serum calcium With the exception of osteoporosis, all other signs, such as bone deformities or tenderness, flabby muscles, retarded development, were relatively slight in cases of hypocalcaemia Severe rachitic deformities were associated with low serum phosphorus The primary sign of rickets was the change in the lime forming salts in the blood, but in the stage of healing the bony changes persisted for some time after the blood had become normal or nearly so Further, it was only when the hypocalcaemia or the hypophosphataemia persisted, in particular if it was progressive, that the skeletal signs of rickets developed But even when the blood changes were persistent concurrent growth was required for the development of rachitic bone change The authors conclude that clinical rickets is chiefly due to deficient retention of the absorbed salts of calcium and phosphorus, and only in a few cases to deficient absorption or supply of these salts This function may be restored by the administration of ultra violet irradiation, cod liver oil, or vitamin D They recommend that 5 c cm twice a day should be the maximum dose of cod liver oil, larger quantities are said to have an injurious effect on the organism

455 Distribution of the Coronary Arteries.

E W Jones (*Practitioner*, September, 1930, p 370) has studied the coronary arteries in health and disease by injection with barium emulsion and subsequent radiography A standard technique is described After the excised heart has been immersed in saline solution for twenty four hours a cannula containing the emulsion is introduced through the cut end of the aorta into the orifice of the artery to be injected The pressure of the injection mass is raised, and filling of the arteries continues for four minutes, after which the heart is kept in formalin for twenty four hours before being x rayed The author has found that in 5 per cent of hearts the left coronary artery is the sole supply of the neuromuscular tissue, 11 per cent of hearts possess three coronaries, the accessory vessel being more commonly found on the right side Marked increase in the vascularity of the left auricle was observed in mitral lesions Accounts are given of three patients who died with the usual manifestations of cardiac infarction, in two of them the findings by radiography after coronary injection are recorded Coronary sclerosis was detected in the first two cases, but not in the third In the second heart there was a large area of fibrosis, but no recent infarction, the left coronary artery was shown by radiography to be extremely narrowed through most of its course, and septal anastomoses were dense In the third patient, who suffered from polycythaemia vera, no chronic coronary disease was present, but thromboses were found in the right and left coronary arteries It was discovered that in complete occlusion the affected vessel throws no shadow on the x ray film, and the related area of myocardium shows no injected vessels Incomplete occlusion due to sclerosis or calcification produces attenuated indefinite shadows contrasting with the smooth outline of the normal vessels A thrombus in process of canalization gives a characteristic appearance on radiography, the shadow being irregular and appearing double in parts, with frequent overlapping

456 Conversion of Carotene into Vitamin A.

N S Cappin (*Biochem Journ*, 1930, xxiv, No 4, p 980) received from Moore some liver oils extracted from rats fed on highly purified carotene The oils were dissolved in ether or chloroform, and their absorption spectra were determined The results were very striking The oils from rats fed on a diet free from vitamin A gave no band in the region of 325 $\mu\mu$, while those from rats given carotene all showed selective absorption in this region The absorption spectra given by this latter group of oils were similar to those shown by cod liver oils Since this band is absent from the absorption spectrum of pure carotene, it follows that the substance responsible for it must have been synthesized in vivo from the carotene It may therefore be concluded that carotene is converted in the body into vitamin A

The SPECIFIC OVARIAN HORMONE
which normally controls and activates the menstrual cycle

SISTOMENSIN
standardised physiologically

dysmenorrhœa menorrhagia, hæmorrhages of puberty and menopause hypoplasia of the uterus, disturbances subsequent to menopause or oöphorectomy

Tablets Ampoules

PROKLIMAN
(Sistomensin Compound)

Association of ovarian hormone with therapeutic agents for the prompt relief of the most pronounced troubles of menopause cardiovascular and nervous troubles, hot flushes headache etc.

Tablets

Hydrosoluble Ovarian Substance

AGOMENSIN

causes hyperæmia of the female genital organs Stimulates the function of the genital glands and menstruation.

Functional amenorrhœa, oligomenorrhœa, sterility, vomiting during pregnancy, etc.

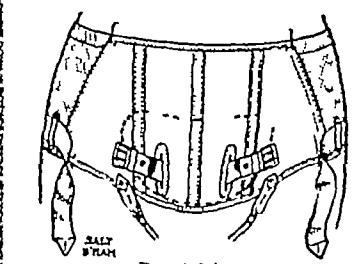
A NEW
QUININE SALT

At the London Medical Exhibition last month the new Salt

QUININE BISALICYLO-SALICYLATE

described for convenience as "QUINISAN" (Howards) was shown for the first time, and very favourably received.

"QUINISAN" (Howards) is a definite chemical compound, occurring as a white odourless crystalline powder practically insoluble in water One four-grain Quinisan Tablet yields the approximate equivalent of 2 grains of quinine and 2½ grains salicylo-salicylic acid. It has proved very valuable in the treatment of influenza coryza tonsillitis etc., and has the unusual property that the salicylo-salicylic acid content is not hydrolised until it has passed through the stomach The gastric irritation common with other salicylic preparations does not therefore arise.



According to eminent medical opinion 12 x 4-grain tablets of Quinisan during 48 hours gave remarkable results in influenza the high temperature and shivering symptoms entirely disappearing by the next day, leaving the patient quite free from fever and discomfort.

Samples of QUINISAN (Howards) and literature will be sent to medical men on application and supplies are now available through the usual wholesale channels.

THE CURTIS ABDOMINAL SUPPORT MODEL N°1

is the only support that gives direct abdominal uplift without cramping or binding the patient in any way

The principle is that of an anterior-posterior pressure and sufficient proof of its efficiency lies in its frequent use in the greater London Hospitals, and by the medical profession who know that it is—

CORRECT IN PRINCIPLE & CERTAIN IN EFFECT

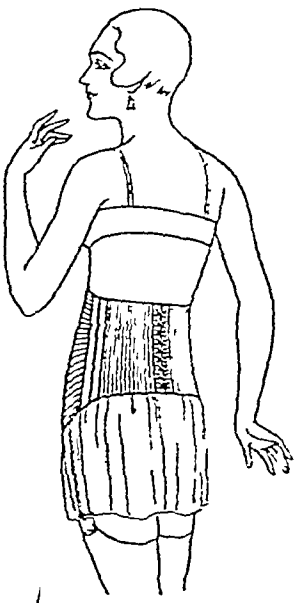
THIS NEW *FLEXIBLE* SUPPORT
IS APPROVED BY LEADING SURGICAL OPINION



FRONT VIEW

At the front of the belt, the thin tricot of great strength can be extended to the required depth so that a gentle pressure is exerted on the full area of the abdomen

Pads can of course, be attached, if necessary

Being Pliable, it Exerts a Firm yet Natural Compression without Restriction

THE Linia Belt represents a definite step forward in modern surgical belt construction, and its patented principles are widely approved by leading professional opinion This belt, designed by anatomical experts, is the result of 25 years' research and experiment in making elastic supports to medical requirements The efficiency and comfort of this method of abdominal control is vouched for by the many prominent medical men who not only prescribe it for their men and women patients, but also adopt it for their own personal use

BACK VIEW

The tough live horizontal elastic of this special tricot can be regulated to the required tension. Thus its lifting and massaging powers are easily controlled As the abdomen resumes its normal conformation, further adjustments can be made by means of the back lacing

THE ACTION OF THE LINIA BELT

The Linia Belt, being made entirely in an exceptionally tough elastic tricot, with firm back and strong extendible front, gives the firm and efficient support so necessary for post-operation wear *without employing any rigid components* Thus it allows complete freedom in movement and breathing Corpulence is reduced by a gentle massage action and a *natural* compression exerted which restores any displaced muscles and organs to their natural conformation. Recommended for post-operation wear in cases of Intestinal Ptosis, Enteroptosis, Visceroptosis, Gastroptosis, Nephroptosis, Cesarotomy, etc.

We invite you to submit this belt to your own tests

We shall be pleased to forward a Linia Belt for your inspection free of charge. *POST ORDERS* can be carried out to your direction on receipt of exact measurement round girth and required depth from pubis upwards. Standard depth 11 inches. *Prices* Standard Model in thread and elastic, 2½ guineas in pure silk and elastic, 5 and 6 guineas. Post free in United Kingdom.

Not a doubt — Wool Protects

Medical evidence* proves wool to be one of the most absorbent of underwear materials, but it is more than that

Other materials, charged with perspiration, allow condensation on the skin at even a slight change of temperature Wool retains the moisture absorbed longer and gives it up more slowly

Dangerously quick condensation, of course, leads to clammy discomfort, worse still, to chills Wool protects against both these

In cases of rheumatism where free perspiration is essential to the elimination of uric acid, and the deposit of damp on the skin a definite risk, the need for wool is especially urgent

There is not a doubt that wool is wiser

Where you advise wool you can safely recommend Wolsey It is pure and soft and is made in a wide variety of styles and weights

WOLSEY

YOU PRESCRIBE LIGHT ABSORBENT UNDERWEAR WINTER AND SUMMER—YOUR PRESCRIPTION IS

JAEGER PURE WOOL!

No medical man would ever recommend heavy, stuffy fabrics worn next to the skin as a protection against cold He knows that anything which fails to allow the impurities in the air round the body to escape—anything which fails to absorb perspiration—is definitely harmful Some form of light porous textu[illegible]ssential for combining warmth with [illegible]aith And it is for that very reason that Jaeger underwear—made of Jaeger pure wool—is so often recommended as the healthiest underwear for all seasons All Jaeger underwear is replaced if it shrinks There are Jaeger Agents in every town

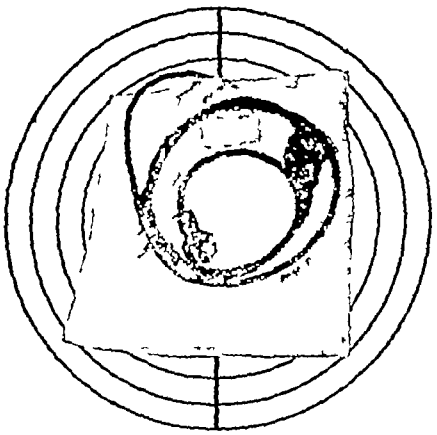
KEROL CAPSULES

Affords relief in all cases of high blood pressure



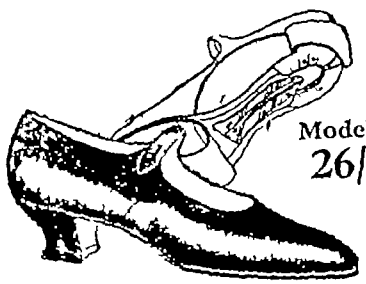
The daily exhibition of Sal Hepatica, the non-habit forming saline purgative, has proved of extreme benefit in all cases of high blood pressure. ¶ Sal Hepatica is also recommended as a rapid means of relieving the stress in cases of dysmenorrhœa. One or two drachms administered on the morning before the expected period, and again at its outset, rarely fails to relieve both the pain and depression. ¶ In chronic constipation the regular exhibition of Sal Hepatica for a week or two restores the daily habit of defecation ¶ Sal Hepatica is not a "patent medicine" and is only advertised to the medical profession.

"Sal Hepatica"
TRADE MARK
the proved medical saline laxative and cholagogue.

¶ Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to

BRISTOL MYERS COMPANY, 112, Cheapside London E C 2



STEADY WARMTH APPLIED LOCALLY IN AN INSTANT

The THERMEGA ELECTRIC PAD takes the place of a hot water bottle in all cases where the local application of heat is prescribed The heat obtained is instantaneous, constant, and easily regulated as desired The THERMEGA pad, no larger than an ordinary hot water bottle, is handy and practical for use while travelling It can be used from any lamp-socket or wall plug at any voltage (100 250) The average cost of current is only 1d an hour (at 6d a unit) A special Thermostat control maintains a level temperature and makes overheating impossible
Ask for demonstration and particulars. Sold by all the big stores, chemists, and electrical dealers, or direct from

THE TREATMENT OF RHEUMATOID ARTHRITIS

This disease which the medical man is increasingly called upon to combat may be successfully treated by the correct application of Pistany radio active Mud Packs

The packs can be applied in the patient's own home if necessary and the treatment may be successfully combined with other physio therapeutic methods

Pistany (Czecho-Slovakia) offers the most effective treatment for the cure of rheumatoid arthritis The properties of Pistany's hot volcanic soft mud are quite peculiar During the season over 26 000 visitors go to this picturesque Spa and statistics show that of 100 of patients only less than 5 do not respond to the treatment—30% are completely relieved and 65% are considerably improved Home treatment can never supersede the cure at the Spa

NATURALLY RICH IN VITAMIN "D"

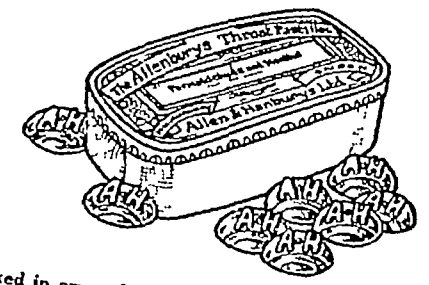
A RELIABLE BASIS

THE above chart shows the large fluctuations in the fat content of liquid milks throughout the year, as compared with the unvarying fat content of "Cow & Gate," which is based on the fat content of average healthy Breast Milk.

Fat content in "Cow & Gate" reconstituted (1 in 8), 3·4 per cent.
Fat content in average Breast Milk 3.3 per cent. to 3.5 per cent.

The fat content of raw milk also varies greatly from day to day. The time of day at which milking takes place also causes considerable variations.

This is in striking contradistinction to the standardized fat content of "Cow & Gate" and affords one of the many reasons why this food is the safest and most reliable alternative when breast feeding fails and why it affords the most reliable basis for Infant Feeding Modifications.



Write for literature and clinical samples of all Cow & Gate Products.

Support HOME Agriculture. Cow & Gate Products are all made from ENGLISH MILK.

COPYRIGHT

SUCCESS achieved entirely as the result of professional recommendation is no matter of chance, but must result from satisfactory experience and from the scientific accuracy of the medicament

OSTOMALT (Ostelin, malt extract, and orange juice) is a dependable source of vitamins A, B, C and D For four years it has enjoyed the increasing confidence of a large and growing body of practitioners

THE CONTROL exercised over the manufacture of Ostomalt, expressed in consistent results, has elected to the [illegible] profession, just as purity and efficacy have [illegible] to the patient

OSTOMALT and 'tonic' are synonymous—its indications are virtually unlimited Whether your patient is infant, youth, or adult, debilitated, convalescent, or merely run-down, Ostomalt will serve you well

OSTOMALT

OTHER OSTELIN PREPARATIONS ARE

Ostelin Liquid (*Ostelin Liq*)
Ostelin Tablets with Calcium
Ostelin Emulsion (*Emuls Ostelin Co*)
Ostelin with Parathyroid Tablets
Colloidal Calcium with
Ostelin Vitamin D Ampoules
Ostol Nasal Spray
Adenolin Capsules

Glaxo Laboratories 56 Osnaburgh Street, London, N W 1

Calcium is not absorbed in the absence of vitamin D

Injection of Colloidal Calcium is a recognised procedure, but it is found that much better effects are observed if vitamin D (Ostelin) is given simultaneously, since absorption of calcium is thus promoted

Colloidal Calcium with Ostelin is thus an ideal combination The therapeutic effect is rapid, and injections can be given daily if desired and continued for a week or more

Colloidal Calcium with Ostelin is indicated in tuberculosis, especially in incipient cases, when it is a most valuable adjunct to routine [illegible] treatment In fracture cases, when it promotes callus formation In *chilblains*, in which it is almost specific and in urticaria, eczema, and other skin diseases associated with hypocalcæmia

Colloidal Calcium with Ostelin vitamin D

For Subcutaneous Injection

In boxes of six 1 cc ampoules 5/- per box
or in 1-oz bottles 10/- per bottle

Subject to usual professional discount

Glaxo Laboratories, 56 Osnaburgh Street London N W 1

appealed

It must be understood that the acceptance by the British Medical Association of an Advertisement does not imply a recommendation, that no responsibility is accepted with regard to the accuracy of the statements therein contained

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

CECIL'S MEDICINE

NEW -- RESET -- REMADE

The Revision No revision of any book published in recent years has been more drastic than that for the *second edition* of this book Every one of the 135 contributors was given *carte blanche* The book *had* to be entirely reset.

The new chapters added include tularemia, snake venom poisoning, atelectasis of the lungs, creeping eruption, oroya fever, brucella abortus infections, essential hypertension, agranulocytic angina, and arthritis

There is no other work on the practice of medicine like this one It is a collection of monographs in *one volume*, each monograph written by an outstanding authority Indeed, the list of authors reads like a medical "Who's Who" Every one of them is a teacher, so that their presentations are in a form specially acceptable to all those interested in the study and *application* of medical knowledge.

This book maintains a very high level throughout its pages Great care has been taken with the dovetailing together of the various contributions into a compact whole and the book is a worthy production of the modern American school of medicine" —LANCET

Octavo of 1,592 pages illustrated By 135 American authorities Edited by RUSSELL L. CECIL, M.D. Assistant Professor of Clinical Medicine Cornell Medical School NEW SECOND EDITION Cloth 40s net.

GRAHAM'S SURGICAL DIAGNOSIS

THE BRITISH MEDICAL JOURNAL says:

It is impossible however in a short review to take each section separately they are of a uniform excellence and there is little to criticize in any of them A bibliography at the end of each chapter is sufficiently extensive to guide those who wish to refer to particular articles while in addition to the usual index at the end of each volume there is a separate index volume which should save much annoyance when reference has to be searched for The publishers have also very wisely placed a small contents table on the covers a plan which might well be adopted in all multi-volume work We are used to copious illustrations in books of American origin and these volumes are no exception photographs and radiograms as well as the simple line drawings have reproduced well and despite their profusion there are few if any redundant or meaningless illustrations The paper is good and the type pleasant while the binding has the strength necessary in a book of reference Altogether this work can be very heartily recommended since it presents the state of modern surgical knowledge in a very fair and unbiased manner it will especially appeal to those who believe that surgery is a science as well as an art

Three octavo volumes totalling 2,750 pages with 1,276 illustrations and a separate Desk Index Volume. By 43 American Authors. Edited by EVARTS A. GRAHAM M.D. Buch. Professor of Surgery Washington University St. Louis. Preset Cloth 150s net.

NORRIS & LANDIS: CHEST and DIAGNOSIS

"OF OUTSTANDING AND RECOGNISED MERIT"

Norris and Landis on Diseases of the Chest is a work of such outstanding and recognized merit that there is no need to commend the fourth edition to our readers But perhaps there are still a few physicians who have not realised the position which some of the work if they are young men just beginning the study of the heart and lungs and especially if they intend to practise they will be well advised to buy a copy at once This fourth edition is an excellent example of carefull revision and discreet additions The book was originally planned and written for the clinician and subsequent slight alterations have rather enhanced its usefulness for him It is we believe the best book of its kind"—IRISH JOURNAL OF MEDICAL SCIENCE.

By GEORGE W. NORRIS M.D., Professor of Clinical Medicine at the University of Pennsylvania and H. R. M. LANDIS M.D., Sc.D. Director of the Clinical and Sociological Departments of the Henry Phipps Institute University of Pennsylvania With a chapter on the *Electrocardiograph in Heart Disease* by EDWARD B. KRUMBHAAR M.D., Director of Laboratories of the Philadelphia General Hospital. Octavo of 954 pages with 478 illustrations some in colour Fourth Edition. Cloth 45s net.

Overnight sterilisation of dentures

A special New *Catadyn Model*

THE illustration you see here shows a new type of Catadyn Steriliser in the form of a Container for Dental Plates, etc It is made in best white glazed Carlton ware, with the Catadyn sterilising elements in the bottom, below a perforated plate The Container is filled with water each night and the dentures placed inside As soon as the water comes into contact with the Catadyn sterilising elements, the Catalytic Dynamic action takes place

Size 3½" × 3" *Contents* 200 c.c

The tests mentioned below were carried out in London

20 Catadyn sterilising elements were placed in 100 c c of water for three hours, and were then removed The water was inoculated with B Coli so that there were 3000 B Coli per c c present Two hours later there were no B Coli present in 1 c c In this steriliser there are over 150 elements, which remain in contact with the water throughout the night

137 of the Catadyn sterilising elements treated 6000 gallons of water Ten of the elements were then placed in 250 c c of water containing 10,000 B Coli per c c On examination 24 hours later, there were no B Coli present in 1 c c 6000 gallons of water corresponds to 27,000,000 c c's In normal use the steriliser will be filled with 200 c c of water each night It will be seen that these elements will give far more than a life-time's service

Apart from dental plates, the Container forms an ideal receptacle for glass eyes The teats of babies' bottles kept in one of these Containers are safe from infection Finally the Steriliser offers a convenient supply of antiseptic water for washing sore eyes, cuts, etc, or for rinsing tooth-brushes

The British Catadyn Company desire to secure the investigation of this remarkable invention by the medical profession and are prepared to send a small Steriliser free for test purposes upon request to the address below

The ordinary price is 6s 6d, postage extra

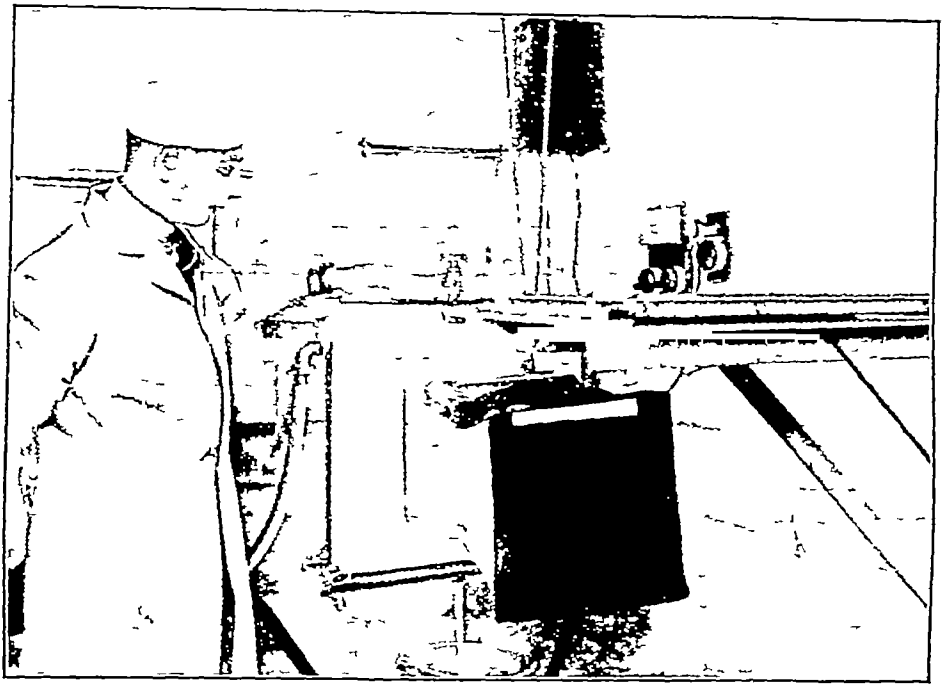
FOUR MONTHS' DIRT—

and still the vital rays come through

A folder about "Vita" Glass called "Health Through Dirty Windows" is now available and will be sent to all interested people It contains, set out graphically and in the briefest possible way, an account of experiments on "Vita" Glass carried out in a notoriously smoky industrial town in the north of England

In brief the experiments show (a) that even on a sunless February day ultra-violet rays are transmitted by dirty "Vita" Glass (b) that "Vita" Glass, coated with four months' accumulation of dirt, still transmits ultra-violet health rays, the transmitting property of the glass being practically undiminished

May we post this folder to you? Write to-day to the "Vita" Glass Marketing Board, 9, Crown Glass Works, St Helens, Lancashire



"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers and Builders

"VITA" GLASS

MICKLEFIELD IRRADIATED MILK

TREATING THE MILK

By this Process—

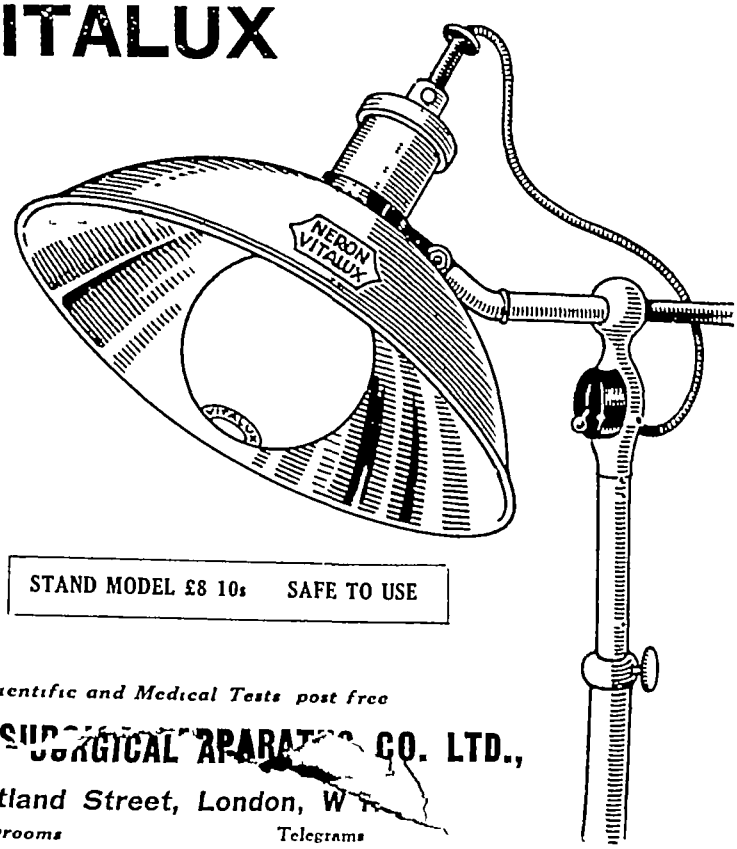
(1) VITAMIN A AND NATURAL FLAVOUR ARE PRESERVED
(2) VITAMIN D CONTENT IS INCREASED 1,800 PER CENT., OR TEN TIMES THAT OF ANY OTHER IRRADIATED MILK.

One pint equivalent in Vitamin D to 600 drops or 12 grammes of average Cod-Liver Oil

A ten weeks test recently conducted at the Infants School Rickmansworth under the supervision of the Medical Officer of Health gave the following results —

(1) 18 children (controls) had their usual ordinary milk.
(2) 29 " 1/3 pint of Grade A (T T) milk five days a week.
(3) 30 " Mickl field " " "

(1) Average increase in height 6.05 in. (2) Average increase in weight 9.72 ozs more than (1)
(2) " " " 6.10 in. (3) " " " 10.9 ozs more than (1)
(3) " " " 7.44 in.



Full particulars appeared in an article in the LANCET January 18 1930 p 127 et seq a reprint of which will be sent post free on request

The milk is delivered every week-day in London, elsewhere by arrangement.

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk, also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity
Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions

Extension of whole lower limbs
Movements about hip joint
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee joint
Inversion and Eversion of foot

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance By thus freeing beds this new apparatus saves its cost many times over

Folds compact for storage or transit in plywood case 3[illegible]in [illegible] 11in

PREVENTION OF CANCER

ONE of the most noted authorities on Alimentary Toxæmia is firmly convinced of the importance of this condition in the production of Cancer

The irritant effects of the stagnating contents of the bowel on the intestinal mucous membrane, accompanied as it often is with ulceration, is obviously a cause of Cancer in the bowel itself According to this writer the toxins absorbed produce atrophic changes in the breast and other organs which are specially prone to be followed by Cancer

There are grounds, therefore, for hoping that the use of the most efficient of all intestinal disinfectants—Kerol—for prevention and cure of alimentary toxæmia, will do much to prevent the occurrence of Cancer

For intestinal disinfection, use KEROL CAPSULES (keratin-coated), they contain 3 minims of Kerol One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

✱ *"The addition of* LACTOSE *to cows' milk is a first essential in an attempt to approximate a natural diet"*

"SUGAR OF MILK is present in human milk to a greater extent than in cows' milk The addition of lactose to the latter, therefore, is a first essential in an attempt to approximate a natural diet," writes a General Practitioner

Humanized milk, i e cows' milk diluted, to which is added up to 5½% of lactose, is increasingly often recommended to mothers unable to nurse their babies

Those responsible for infant welfare in this country will welcome the news that sugar of milk is now available to the public, in sealed 1-lb packets guaranteed chemically pure, at a cost of 1/5½ With Serolac Brand of Sugar of Milk, humanized milk is not only preferable, but costs approximately 25% less per week than the average prepared baby food

* * *

Full particulars as to sources of supply, etc, from Whey Products Limited, Haslington, nr Crewe — Manufacturers of Serolac Brand of Sugar of Milk.

PHYSIOLOGICAL TREATMENT OF CONSTIPATION

Total extract of the glands of the intestine Biliary Extract-Agar-Agar-Selected Lactic Ferments

TAXOL

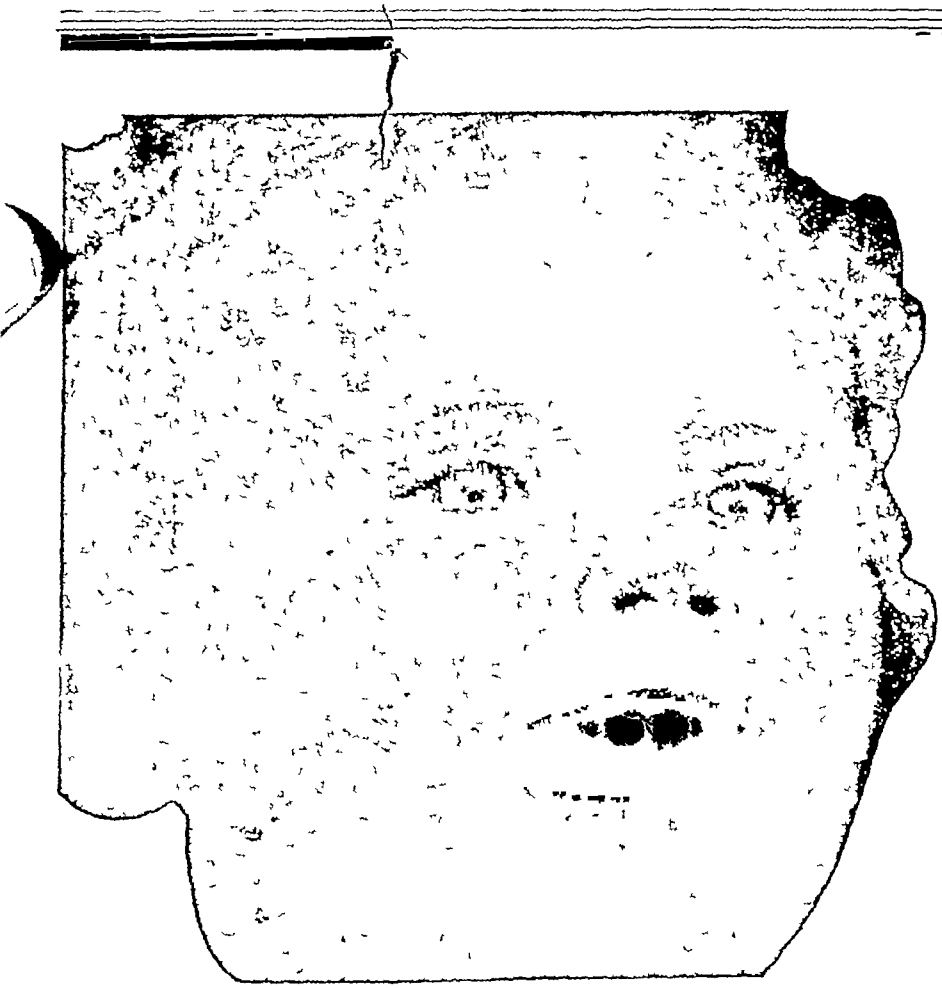
LABORATOIRES REUNIS LOBICA, 46, Avenue des Ternes, PARIS.

S.U.P. 36

Experience in hospital and in private practice shows that treatment with SUP 36 is of remarkable value in cases of influenza, feverish cold, tonsillitis, pneumonia and other febrile inflammatory conditions SUP 36 reduces temperature rapidly and clears up threatening broncho-pneumonias

Recently SUP 36 has proved useful in a case of glandular fever in which the patient was running a temperature of 103° (*B.M.J.*, November 8th, 1930, p 779)

The following typical report shows with what remarkable promptness such inflammatory conditions with accompanying pyrexia respond to injections of SUP 36



"Temperature 104°; patient cyanosed and very ill. At 11 p.m gave S.U.P 36. At 7 a.m. temperature was 99°. Patient continued to progress and never looked back."

SUP 36 is issued in solution in ampoules ready for intramuscular injection; it is obtainable from the leading pharmacists

BONE-MARROW IN ANAEMIA FROM HAEMORRHAGE

W Borchardt (*Deut med Woch* March 28th 1930 p 521) records the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood. In the first series some of the animals were fed with rib-marrow others with marrow from the long bones. Control animals received a corresponding amount either of fat or of liver extract The basal diet in each case contained a sufficiency of iron (5 mg per cent). Only the animals receiving the red rib-marrow showed a definite increase of weight and their haemoglobin formation was more rapid than that of the others. In the next series the experiment was repeated but the iron content of the diet was reduced to 1 4 mg per cent The result was similar but more striking the dogs receiving the rib-marrow regaining their haemoglobin far more quickly than the others.

THIS extract from the "Epitome of Literature, published in the BRITISH MEDICAL JOURNAL dated May 3rd last is important as representing in 1930 a complete justification of the formula upon which

Roboleine

THE FOOD THAT BUILDS THE BODY

has been produced without variation during the past twenty five years

The success of ROBOLEINE is thus due to intelligent anticipation and to consistently maintaining the highest possible standard of manufacture

Medical Practitioners are asked to satisfy themselves of the merits of ROBOLEINE for which purpose testing samples will be gladly sent upon request.

Infantile Diarrhoea.

A letter recently received.

The Medical Adviser of Messrs Kaylene Ltd
London

Dear Sir

The case to which I referred was a child of six months who was brought to me after having treatment elsewhere for diarrhoea and vomiting The child was practically a skeleton and apparently had been vomiting everything—even medicines—for many days The mother thought and her friends thought the child was dying and I happened to be the nearest doctor I gave the child one teaspoonful of plain Kaylene in plain cold boiled water and kept the mother and child in my consulting room to watch effects If ever a child was drawn from the jaws of death I think that little sufferer was The Kaylene was retained the gasping steadily lessened the haunting look of that child's eyes became less distressing in fact the change for the better was so pronounced that in an hour's time I allowed the mother to take the child home

Fortunately I had sufficient Kaylene by me (a sample you kindly sent) and I gave the mother sufficient to give a teaspoonful every hour during the night The chemists shops were all shut by this time I gave full instructions—strict instructions—not to give anything else but Kaylene and plain cold boiled water as I had done

In the morning the mother came to see me and informed me that only twice during the night the child had loose stools but no vomiting and had slept fairly well The child had other two loose motions during the day but not offensive ones like all the other stools In the evening the child cried—the first time for two days—and as she looked and was so much better I gave her some white of egg with plain cold boiled water Still improving I kept her on this for three days She was doing well and I then allowed her milk She made a complete recovery and there can be no doubt whatever that Kaylene saved the child's life

Yours faithfully

SCIENTIFIC DIETETIC DETAILS

Recent advances in diet therapy have led to the complete reversal of earlier methods—the almost total exclusion of starch from the dietary of diabetic patients is now recognised as fundamentally wrong The modern dietetic treatment of diabetes demands that bread and other farinaceous foods shall contain carbohydrates up to, but not in excess of, the ascertained degree of tolerance, whether Insulin is used or not Indeed, in all disorders of the alimentary tract, from whatever cause, an adjustment of the protein and carbohydrate on defined and accurate lines is admittedly essential

Energen starch-reduced and protein-increased products enable the physician to prescribe definite proportions of carbohydrate, protein, and fat to patients suffering from Indigestion, Rheumatism, Obesity, and similar complaints, the composition in grams and the total calorie value being stated on every packet

A sample packet of BISMEAL the balanced Energen Breakfast Food sent post free

Dietetic monographs diet tables for diabetes—revised in accordance with the recent report on the Carbohydrate Content of Foods prepared for the Medical Research Council (Privy Council) by McCance and Lawrence—diet tables for obesity and light diets, and samples, will gladly be furnished to Members of the Medical Profession

REGETHERM POULTICE

(Cataplasma Kaolini. B P C)

CLEAN & CONVENIENT IN USE

More certain in its action than the old-fashioned poultice

The healing action of Regetherm Antiphlogistic Poultice is governed by its ability to prolong and maintain an even degree of heat over a lengthy period Moreover the ingredients are so balanced that this action does not set up any counter irritation but allays pain ensures an even circulation through the contested areas and thus induces natural and pain free rest

The Medical Profession will appreciate the fact that the action of Regetherm Poultice is much superior to that of fomentations or linseed poultices and can be relied upon as an efficient aid in the treatment of all types of inflammation—whether local and superficial or of deep seated origin

Vitamin foods and physiological balance

The influence of food upon the maintenance of health is in direct relation to the manner in which the various essential food factors are present in correct physiological balance No one of these food factors alone, however essential in itself, can bring about the complete physical development that Virol does For in Virol the various Vitamin foods are in properly balanced proportion with the all-important mineral salts, and are blended into a delicate and palatable emulsion, that is immediately acceptable and easily assimilated—even in the most delicate conditions

No other food gives the same results, for no other food contains all the ingredients of Virol in the same scientifically balanced proportions.

INSULIN (BOOTS) is prepared in the Laboratories of Boots Pure Drug Company Ltd, under Licence No 19 (Therapeutic Substances Act, 1925) of the Ministry of Health
It is made from selected ox pancreas which is subject to the strictest examination before use
The company possesses specially equipped Analytical, Pharmacological and Bacteriological Laboratories in which all the tests required by the Therapeutic Substances Act are carried out Each batch of Insulin (Boots) is tested for potency against the International Standard Insulin and also for sterility — these tests being carried out both before and after filling into ampoules
A sample of each batch, together with a report on the potency and bacteriological tests made, are submitted to the British Medical Research Council whose certificate of correct strength and of sterility is obtained before the batch is issued

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl salicylic acid possesses a notable disadvantage Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach ,Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced

"Alasil" completely overcomes this objection By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract "Alasil" is therefore a triumph over acetyl-salicylic acid It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time Analgesic, Antipyretic and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore

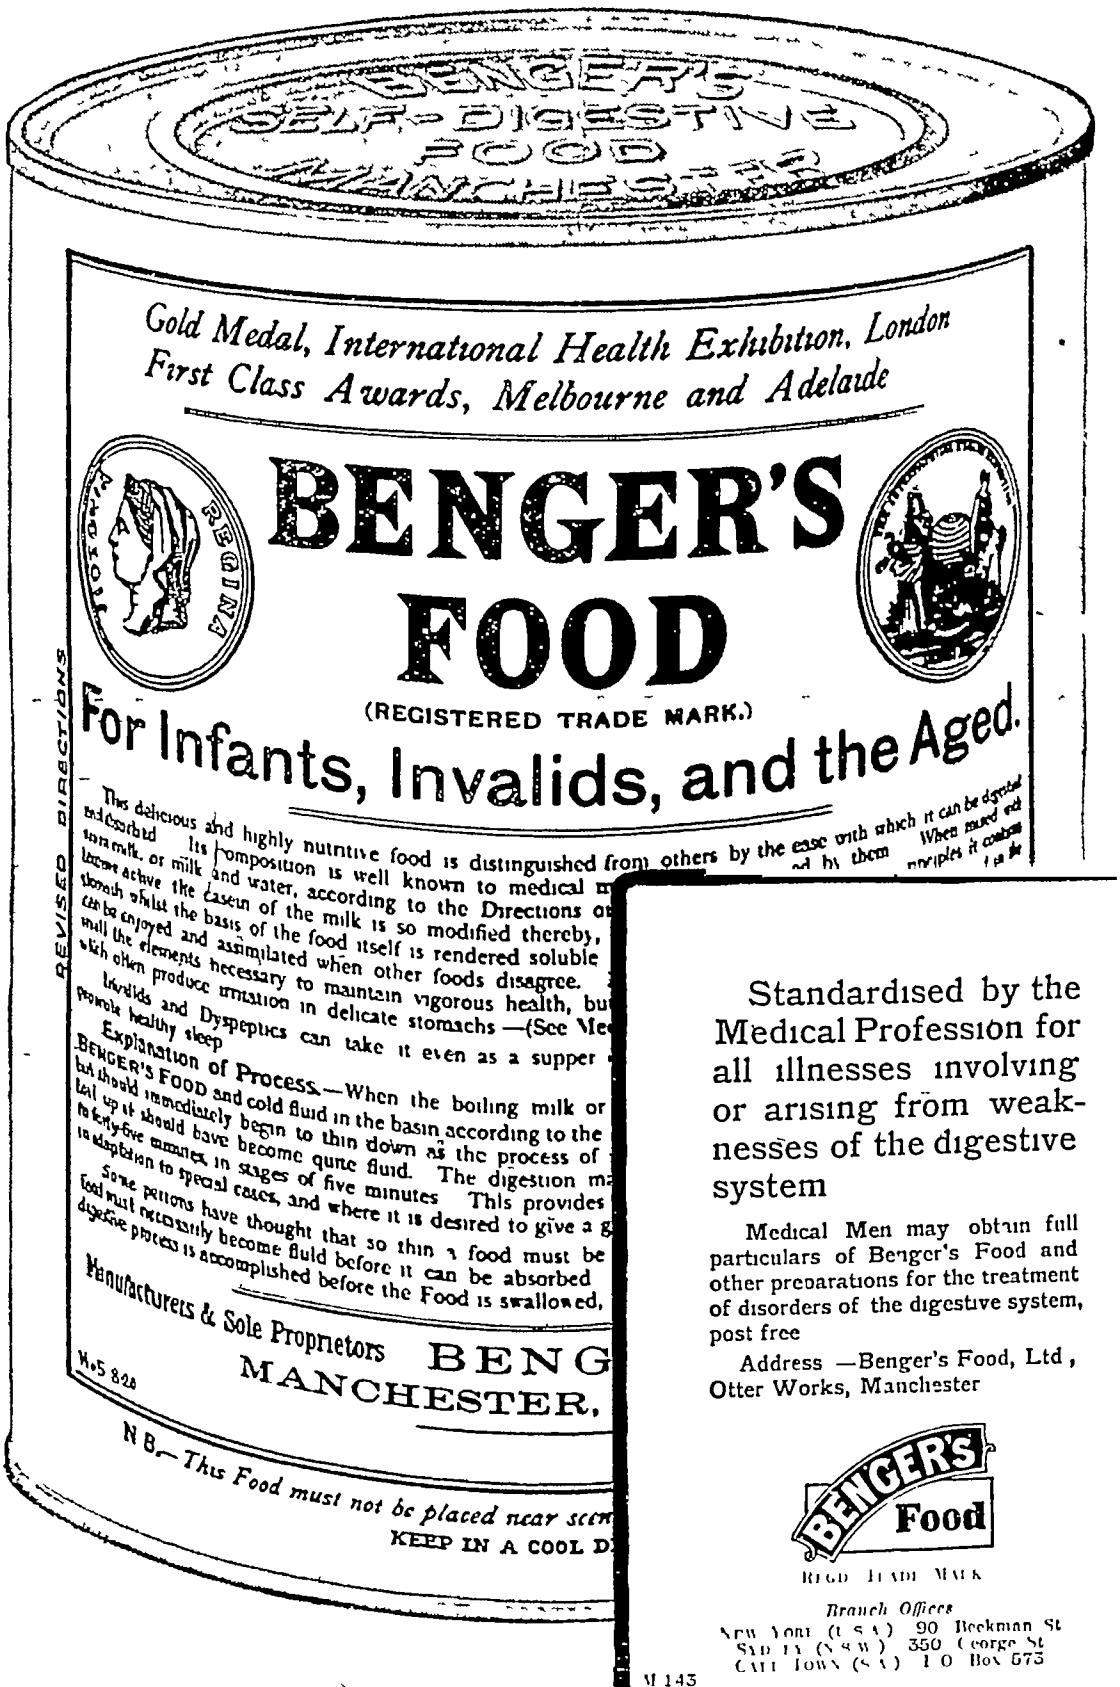
DIMOL SNUFF

A convenient and efficient bactericide in all infections of the upper respiratory tract, especially as a preventive to invasions by the germs of

The Common Cold	Chronic Nasal Catarrh
Bacillus Influenzae	Pneumococci

LABORATORY TESTS.



Dimol Snuff has a coefficient equivalent to 30% pure phenol—that is, it is as active as a bactericide as pure phenol diluted with twice its volume of water—a strength of phenol of course quite intolerable in the respiratory tract

Dimol Snuff diluted with 10 times its bulk of mucus will kill

Pneumococci in 30 seconds
B influenzae in 30 seconds.
M catarrhalis in 35 seconds.
Streptococci in 40 seconds.

Prices and particulars will be sent on application to

The Alkalies in Respiratory Diseases

Recent work on influenza, the common cold, pneumonia, and catarrhal fevers in general, has served to focus attention on the value of the alkalies in the treatment of these infections It has been found that a system saturated with alkalies increases the resistance to bacteria During the influenza epidemic of 1918, patients so alkalinised showed a low mortality rate and, in the main, a quick convalescence.

BiSoDoL, a balanced alkalinising agent, may be effectively employed to combat acidosis and build up the alkali reserve without upsetting the stomach or causing alkalosis

The utility of BiSoDol as an antacid in hyperchlorhydria, gastritis, gastric and duodenal ulcer, has been abundantly demonstrated It has also been given with marked success for the control of cyclic vomiting and the morning sickness of pregnancy.

BiSoDoL

Samples will be gladly sent to Physicians on request.

When vitality is at its lowest and solid food is intolerable—

THESE ESSENCES STIMULATE WITHOUT THE SLIGHTEST STRAIN ON THE DIGESTIVE ORGANS

IN any dangerous illness a condition often arises which makes the taking of solid nourishment impossible The need then for a form of food which can be absorbed rapidly, without effort, is imperative!

Scores of leading practitioners today find Brand's Essences an ideal preparation in crises of this kind Out of hundreds of doctors interviewed within the last few months, 99 per cent. said they recommended this product

Palatable, easy to take, the delicious jelly can be assimilated without the slightest strain on the digestive organs

For Brand's Essences are powerful exciters of the gastric juices Hidden in them are those very elements of meat which rouse the secretions of the stomach to digestive action instantly

And no substance which could hinder quick assimilation is added They are simply the pure essence of the finest fresh meat — *conserved in its natural form* without the addition of any colouring, flavouring, or gelatine

So rapidly can these Essences be absorbed that in states of exhaustion they stimulate and restore vitality almost immediately

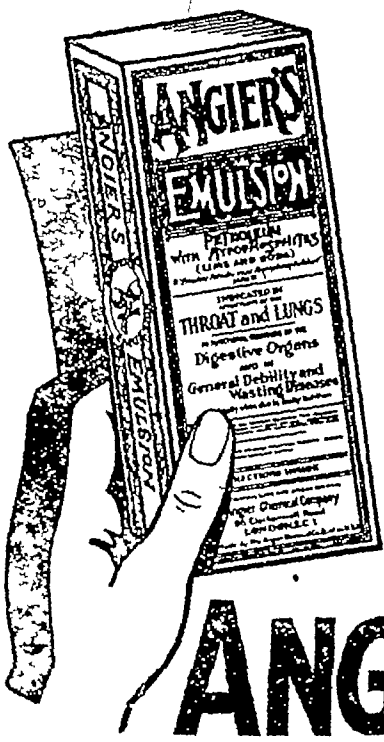
During recovery from illness, they are invaluable in rousing appetite and preparing the patient for more solid diet.

BRAND'S ESSENCES

(Made only from the finest English Beef, Chicken and Mutton)

Brand's Essences are subjected to meticulous laboratory tests to ensure the highest possible standard of quality and purity

They are prepared under ideal hygienic conditions, under scientific control, and their purity and proved advantages in illness have made them famous for a century Brand's Essences are obtainable at chemists and stores throughout the world in tins and glasses On receipt of a professional card, samples of the Essences will be sent you at once Write Dept F 16, Brand & Co Ltd., Mayfair Works, Vauxhall, S W.8



Recent investigation shows that the following percentages of Doctors Dentists Nursing Homes and Hospitals are recommending Brand's Essences

DOCTORS	99%
DENTISTS	92%
NURSING HOMES	78%
HOSPITALS	61%

Bronchitis, Sub-Acute and Chronic.

There is a vast amount of evidence of the most positive character proving the efficacy of Angier's Emulsion in sub-acute and chronic bronchitis It not only relieves the cough, facilitates expectoration and allays inflammation, but it likewise improves nutrition and effectually overcomes the constitutional debility so frequently associated with these cases Bronchial patients are nearly always pleased with Angier's Emulsion, and often comment upon its soothing "comforting" effects

Pneumonia and Pleurisy.

The administration of Angier's Emulsion during and after Pneumonia and Pleurisy is strongly recommended by the best authorities for relieving the cough, pulmonary distress, and difficult expectoration After the attack, when the patient's nutrition and vitality are at the lowest ebb, Angier's Emulsion is specially indicated because of its reinforcing influence upon the normal processes of digestion, assimilation and nutrition

In Gastro-Intestinal Disorders

of a catarrhal, ulcerative, or tubercular nature, Angier's Emulsion is particularly useful The minutely divided globules of petroleum reach the intestines unchanged, and mingle freely with intestinal contents Fermentation is inhibited, irritation and inflammation of the intestinal mucosa rapidly reduced, and elimination of toxic material greatly facilitated

An Address on REST, WORK, AND PLAY IN HEALTH AND DISEASE

BY

SIR E FARQUHAR BUZZARD, Bt, K.C.V.O., M.D. F.R.C.P.

REGIUS PROFESSOR OF MEDICINE OXFORD UNIVERSITY

When our President honoured me with an invitation to address you to-day, I did my best to visualize the conditions under which I should have to carry out my task and came to the conclusion that work and play would be appropriate subjects for discussion at this meeting and that rest on this, the last day would not be without its seductive appeal to some of us. Questions in regard to indulgence in work, play, and rest are so often put before us in our professional capacity and are so often answered with more respect to tradition than to experience, that they deserve the reconsideration due to all possible factors in the production or maintenance of health and disease. While it is true that play and rest are generally and indeed not unpopularly, recognized as prophylactic and remedial agents of no mean value the position of work is more precarious in the minds of the profession and of the public and it may be that it has earned a reputation for etiological mischief based on somewhat slender evidence. It is not surprising—it is only in accord with human nature—that when the cause of an illness is in doubt, over-indulgence in work is a more acceptable verdict than over-indulgence in other things, such as food, drink or tobacco. But a verdict which is most welcome is not always the best founded, and the medical profession bearing in mind the well-recognized good health and longevity of its members should surely hesitate to agree that over-working can be held responsible for disease or death, without a careful examination of the testimony supporting that doctrine.

It might at first sight be presumed that our knowledge of the physiology of the nervous system provides us with principles sufficiently reliable to guide us in prescribing work, rest, or play, but helpful as such knowledge is, it is not yet equal to solving all the problems with which we are confronted and we must still look to clinical experience for light and learning.

On the other hand, clinical experience is of little value unless it is subjected at every step to careful analysis and the *post hoc propter hoc* process of reasoning used with critical economy. If this rule were as conscientiously observed as it should be by all who have had the advantage of a scientific training, the value of time, the lapse of time as an important ingredient of treatment would not be so often overlooked. And giving credit to time is, after all only an alternative to paying the tribute due to nature's share in repairing structure and restoring function. This sounds like a platitude when addressed to those who have wrestled successfully with the courses and inquisitions of the medical curriculum but if the critical faculty inculcated by the latter survived more generally for a few years the ordeals of practice, we should dispense with at least one-half of the therapeutic measures and concoctions which are prescribed from time to time at the dictates of a prevailing fashion or of an enterprising firm. Is it not true to say that while the time factor is usually estimated at its proper value in relation to certain morbid conditions, the length of which is more or less defined, such as a specific fever or a bony fracture, it is undeservedly neglected in relation to other common disorders whose course is less easily foretold, such as an attack of sciatica or a broken heart? I need only remind you of the craze for rest cures as the universal remedy for all psychoneuroses thirty years ago in order to illustrate the dominating influence of fashion on medical practice. The employment of rest in the treatment of an anxiety neurosis, as in the treatment of a damaged joint, has indeed undergone a revolutionary revision in recent years. My chief object to-day is to examine our established practice in regard to the prescription of work, rest, and play, and to question some of the principles which govern it. As the nervous system is more concerned with these matters than any other, my illustrations will be largely drawn from its functional and organic disorders, and particularly from those which call for specific advice in the regulation of mental and physical activity.

The Prescribing of Work

Epilepsy is one of the commonest disorders of the nervous system, and one which every practitioner is called upon to treat. I expect that we shall all agree that the following story is typical of many presented to us. A boy of 14 years of age, with a previous history of average good health, and with apparently good prospects, has a fit, followed a few months later by another. Perhaps the first has been disregarded, or attributed to some quite inadequate cause, but the second has created alarm, and awakened the parents' minds to the possibility that their son's whole future career is jeopardized. In this atmosphere of panic it is not unnatural, and certainly not unusual, to find that some drastic alteration in the patient's life is advocated. He is to be taken away from school, his brain must be freed from all the strain of lessons and he is to be allowed to run wild for a year in the open air. The chief advantage of such advice is that it sounds eminently sensible, and yet experience teaches us that it may have disastrous results from more than one point of view. In the first place, there is no justification for believing that it will diminish the liability to recurrent attacks, in the second place, it interferes with and interrupts the normal progress of intellectual and moral development and discipline, and thirdly, it suggests to the patient's mind that he is not as other boys are, with the result that a sense of inferiority is easily acquired. Even these disadvantages might be worth incurring if we did not know that speaking generally, an epileptic subject is less liable to fits when his attention and interest are fully occupied than when his thoughts are allowed to run loose. I have known so many children of both sexes overcome the liability to fits when their ordinary educational career is proceeded with that I am convinced that work can rarely exercise any prejudicial effect. In other words, regular and moderate hours of work and play may safely be regarded as an essential part of the treatment, and if, when combined with medicinal therapy, they are unsuccessful, the outlook is certainly grave. Perhaps a general recognition of this truth might influence more schoolmasters to co-operate in rescuing boys and girls from the menace of a very terrible affliction. Undoubtedly, not a few regard the epileptic brain as an organ which should not be allowed to exercise its normal functions, an opinion to which I can give no support. Our ignorance of the pathology of the epileptic habit is so profound that we are obliged to seek elsewhere for guidance in preventing its establishment, and I feel convinced that much depends, in a great many cases, on the way the patient is handled when the first symptoms of this nervous disorder make their appearance. While it is one of the few diseases in which the influence of drugs properly administered, is of paramount importance, success in treatment is enormously favoured by interfering as little as possible with the normal routine of cerebral activity—in other words, with the ordinary ration of work.

Let me turn to another common disease of the nervous system, of which the pathogenesis is still not established. A young woman, between 20 and 30 years of age engaged in teaching develops diplopia and a disability of one limb leading to a diagnosis of disseminated sclerosis. Vision returns to normal and the defective limb recovers its function in the course of a few months, but the diagnosis has been made and the patient's relations know that a threat of recurrent disabilities overhangs the girl's future. The doctor is asked what steps can be taken to prevent relapses, and in many cases he will advise the relinquishment of her work and the avoidance of all mental and physical exertion. Again the advice sounds all right, but can it be justified by any reliable evidence? My clinical experience leads me to believe that we are without any satisfactory

Delivered on the occasion of the Annual Meeting of the British Medical Association, Winnipeg 1930.

knowledge as to what factors are responsible for the appearance of fresh plaques in this disease, that relapses may be delayed for five, ten, or fifteen years, and that they are likely to appear at the end of a long restful holiday as in the middle of a strenuous term's work. If this is the case are we justified in asking our patient to give up her career, her interest, and her chief source of happiness in life? I can recall so many patients who, in spite of carrying the label of disseminated sclerosis, have led active and useful lives over a number of years, that I should always hesitate to advocate one of idleness. I cannot believe that normal activity or even normal fatigue of the nervous system has any prejudicial influence in such cases, and I am sure that the patient's interests are best served by the encouragement to resume her normal occupation and habits. One particular incident which has always been fixed in my memory is worth recording in this connexion. A young woman, who had suffered from symptoms of disseminated sclerosis and had temporarily recovered, was employed in a large shop or store. The building in which she worked caught fire. She escaped with difficulty, although several of her companions lost their lives. In spite of this emotional experience, followed by months of particularly hard work, she remained quite well, and it was not until a year or two later, while spending her summer holiday at the seaside, that she developed further symptoms of her disease. Before leaving the subject of disseminated sclerosis I must make it clear that I do not advocate activity during the acute phases of the disease. On the contrary, rest must be regarded as a first essential in favouring the complete or partial restoration of function in damaged parts of the nervous system, a process which may be safely entrusted to time and nature, at any rate in cases of recent origin.

Paralysis agitans, or Parkinson's disease, affords another example of organic disorder of the nervous system in the handling of which the question of work and rest has often to be answered. Here we have to deal with a chronic progressive defect of function of a part of the central nervous system, the cause of which is unknown and the course of which we are entirely unable to influence by any method of treatment. A man of 50 engaged in business, and blessed with other interests and hobbies, develops the characteristic facies and tremor of the disease, and quite naturally asks whether he should give up his work and lead a more restful and sedentary life. In my opinion the answer should be definitely and firmly in the negative. The devotion of time and money to the many curative treatments which will be pressed upon his notice can only lead to a long series of disappointments, and the more leisure he has at his disposal the more will he become preoccupied with his affliction. If he is well advised he will carry on with his work and his play regardless of the fact that he is slower and less active, and as far as possible refuse to recognize his limitations. Only by taking, and persevering in, such a line of action will his life be made tolerable, and we have no right to suggest that by sacrificing his work or his recreations he may expect to render his disabilities less irksome. There is nothing more pathetic or tragic in medicine than the sight of a patient suffering from paralysis agitans who has given up his lifelong interests in the vain pursuit of a cure, and it is difficult to exaggerate the importance of giving the right advice in these cases. There is nothing easier for the medical attendant to advocate than avoidance of mental and physical activity, the very attributes which it is most desirable his patient should foster and preserve.

The observations I have offered on epilepsy, disseminated sclerosis, and paralysis agitans may be applied with diminating modifications to many other organic disorders of the nervous system. They uphold the principle that work, the normal activity of the nervous system, is not contraindicated even when parts of it are damaged or out of order, so long as the latter are not subjected to an unreasonable amount of strain. They are opposed to the tradition that because a patient is suffering from a disease of the nervous system all the multitudinous functions of the brain should be put in irons and allowed to rot. After all we encourage other organs to carry out their functions even when they are damaged by disease. Work is a physiological, not a pathological, process, and its output is not only valuable in itself, but carries with it a psychological influence of paramount importance to the patient's insight, his outlook on life, and his general welfare.

Rest in Therapeutics

If discrimination is called for in prescribing work, it is equally necessary in prescribing rest, and a review of our practice in the latter and of the doctrines which have led up to it may not be without profit. In the first instance, I propose to deal with rest as it is employed in the treatment of psychopathological conditions, and the word "rest" will, for the moment, mean confinement in bed with partial or complete isolation. May I remind you again of the fact that for a period of years rest cures were regarded as the orthodox method of treating neurasthenic and psychoneurotic disorders, and may I suggest that the practice has become less fashionable because experience has exposed its failure to deal effectively with all cases? It may be that rest cures still have their value, and it may be that we are still not quite competent to judge when complete rest is indicated or contraindicated. The rest cure prevailed at a time when our insight into so-called "functional disorders" was not so clear as it is now, and there can be little doubt that it was employed indiscriminately for a number of conditions which differed in origin and which therefore called for different treatment. Moreover, when it successfully attained its object, and relieved the patient, there was always some doubt as to the relative share of the prescribed rest, of suggestion, and of the lapse of time in achieving the result. The bulk of "functional disorders" can be divided for practical purposes into three categories: (1) the anxiety neurosis, (2) hysteria, and (3) the milder forms of the manic-depressive psychosis. Hysteria may be dismissed from further consideration here, because its treatment is essentially based on psychotherapy and rarely demands serious rest. In fact, we may be assured that a rest cure unassociated with psychotherapy would be singularly unsuccessful in curing the frank hysteric.

In spite of our improving insight into psychopathological disorders, the differentiation of an anxiety neurosis from a mild manic-depressive psychosis is not always made with the sharpness it deserves, and in view of its importance for the purpose of treatment a short consideration of the problem will not be out of place. Certain symptoms are common to both conditions, and so lead to mistakes in diagnosis and to inappropriate treatment. Depression, insomnia, failure of concentration, decision, and memory, exhaustibility and restlessness, are complained of both by the neurotic and by the psychotic patient, and particular attention must be directed to one or two of these symptoms in order to make a diagnosis. The depression of the neurotic patient is variable and sometimes dispersible, it is made worse by fatigue and may be alleviated by distraction. It is attributed to the faults of others or to unfortunate circumstances, and it is very rarely of a quality or intensity which leads to suicide. The depression of the psychotic patient, on the other hand, is that of a person who is incapable of interest in anything. It involves loss of natural affections and appetites, and cannot be dissipated by distraction. It is associated with self-accusation and remorse for some real or imaginary wrongful act or behaviour in the past, and no arguments will avail to correct the obsession. It is at its worst in the early morning, when morbid and suicidal thoughts are apt to be translated into deeds. With the neurotic patient sleep is always a difficulty, and he is inclined to lay the blame for his sufferings on insomnia. With the psychotic patient sleeplessness is not so invariable, and indeed may sometimes be self-inflicted, owing to his dread of the terrible depression which overtakes him on waking. The one fears the night, the other the day. Further consideration of the distinctive characters of these two conditions would be out of place and I have said enough to indicate the features concerned with the question of the rest cure. Harking back to the success and failure of the rest cure it is easy to realize that many a patient suffering from psychotic depression was well protected and cared for during the period of his illness, and that the necessities

for his recovery—rest encouragement and time—were all available, if his pocket could stand the strain We know that such patients always recover in time, that sympathetic care rather than active treatment conduces to safety, and that psycho-analytical attacks are more of a danger than a help The patient with an anxiety neurosis is a different problem Rest may or may not be helpful depending on the state of exhaustion prevailing at the moment he comes under medical attention but recovery will depend more on skilled psychotherapy than on the prescription of so many weeks' confinement to bed In fact, we must never forget that rest tends to narrow and to limit the patient's environment, and so encourages preoccupation and introspection

I have memories of the anxiety neurotic patient emerging from a prolonged rest cure unrelieved, and I can recall certain patients with psychotic depression being released too soon from allotted periods of rest only to end their lives The question of rest in the treatment of functional nervous disorders is not therefore so simple of solution as it at first appears Its value can only be estimated accurately in the light of a correct diagnosis The rest cure has fallen into comparative disrepute now that we realize that rest is a useful ally but rarely the essential agent in the relief of the "psychopath" But a rest and a rest cure are not synonymous terms, and the former is loosely used to indicate relaxation and recreation as well as physical torpor In this way rest from work may include recreation, which is often play, a species of activity the reverse of restfulness In the maintenance of health there is much variation among individuals in regard to the amount of sleep or complete repose required in order to avoid undue fatigue It would seem that every individual is endowed with his own capital of nervous energy on which to draw and that over-expenditure is attended by symptoms with which we are all familiar We also recognize that prolonged activity of one part of the nervous system may lead to fatigue of its particular function or reactions, without unduly depleting the capital of nervous energy or interfering with the function of other parts It is on this principle that the healthy person, consciously or unconsciously, regulates his life in other words he employs various parts of his nervous system in turn without tiring out any one of them Unwittingly he recognizes the physiological law that reactions are more easily fatigued than the common paths through which they are executed, and that one set of reactions may regain their functional integrity after fatigue, while others occupy the field of action The repetition of one operation may in the end produce what is called specific objective fatigue, a form of fatigue which does not interfere with the performance of another operation On the other hand general objective fatigue which may be induced by one kind of work may affect the output of an entirely different kind of work to a small extent Experiment has shown however, that fatigue produced by mental work is evanescent the mind being restored to efficiency by sleep or by short interruptions of its activity The phenomena attributed to overwork are more often and more justly to be ascribed to preoccupations of a personal character amounting to an anxiety neurosis According to Gillespie 'Clinical experience bears out these experimental findings Mental exhaustion brain strain from overwork and the like can be safely discarded as a hypothesis in 999 out of 1 000 cases The apparent mental incapacity in such cases is nearly always the result not of intellectual effort but of anxiety or a kindred emotional disturbance This is brought home very dramatically in the sudden recovery of persons complaining of brain fag' which has perhaps limited their work to periods of less than an hour each when a source of worry is removed"

Except during sleep, the mind is always active, and it is customary to allot a certain number of hours in each day to a specific form of work mental or physical the remainder being spent in recreation The latter may be of various kinds, according to the interests of the individual the pursuit of art science or literature or participation in sport or games They all involve cerebral activity and derive their beneficial effects from the fact that the centre of interest and action is temporarily changed The player of a game, for instance is refreshed by following his favourite ball because his centre of interest is altered, other reactions are initiated, and his mind is preoccupied with problems entirely different from those associated with his work It is probably not an exaggeration to say that these factors are of much greater importance than the physical exercise the game involves in promoting a state of good health Realizing, as we must do, that interest depends largely on inborn facility, and that without interest the benefit of recreative pursuits is greatly discounted, we should be well advised not to make a fetish of games as the only means of securing relaxation from work "Take up golf" is in danger of becoming a tabloid preparation, too easily prescribed, readily swallowed, and not always producing the desired results To many, a change from one form of mental work to another is much more recreative than the pursuit of a ball whose flight and destination are of much less interest than those of a moth or a bird It is certainly true, moreover, that a very small amount of muscular exercise will suffice for the maintenance of good health It is sometimes alleged, and the allegation sounds sensible, that the crowds of people who watch football or baseball on a Saturday afternoon would be better employed playing some game themselves. As their interest cannot be doubted, and as they spend their time in the open air, the conditions favouring relaxation and recreation appear to be adequately fulfilled On the other hand, it must be admitted that their interest is often more financial than sporting and therefore predisposes to the development of an anxiety neurosis, which may not always yield to the recuperative influence of the next week's work Incidentally it is our duty to expose the fallacy that the good health, especially the mental good health of an individual is directly dependent on the size of his muscles Physical exercises, unassociated with cerebral activity and recreation, are no panacea for mental exhaustion, on the contrary, they constitute a super-tax on the nervous system, and encourage the musculature to make further and uneconomic demands on its limited sources of energy Muscles are intended to be the servants not the masters, of man, and the efficiency of their service must be measured not by their bulk, but by the speed and accuracy of their response to the demands of the nervous system

Perhaps, in order to anticipate remonstrances I ought to explain that these remarks are not intended to be an attack on physical jerks as a whole They are directed rather against the craze for various systems of exercises advertised to cure all disorders whether of the liver or of the nervous system, and largely taken up by the sedentary worker lacking a hobby, in the vain hope that they may dissipate his weariness of spirit He may be unaware that this weariness represents a subconscious inhibition of a particular activity in other words, a psychological state of staleness rather than one of real exhaustion

Relaxation

While the question of recreation is complicated by personal idiosyncrasies, and must be answered only after careful consideration of individual needs that of relaxation deserves perhaps more general examination Remembering the remarkable capacity shown by nervous centres to recuperate rapidly from fatigue and taking into account the natural aptitude possessed by certain individuals for long periods of intense work, interrupted by comparatively short spells of complete repose, it may be asked whether more could not be done to acquire and cultivate such enviable powers of alternating concentration and relaxation The cult of relaxation is no new thing but like most cults may have lacked the recognition it deserves owing to the enthusiasm of its protagonists At any rate we are all familiar with individuals who appear to wear themselves out by maintaining a continuous state of restless but unproductive activity It may be that a scientific study of complete mental and physical relaxation, its methods of induction, its proper relationship to work and play, and its value in everyday life might show that it is a habit the acquisition of which is worthy of becoming an item in everyone's education At any rate relaxation, like work and recreation, is not

likely to escape further study and we may perhaps look forward to the time when we shall be able to switch off our nervous energy as readily as we do our wireless or our electric light, and so regulate its consumption to our best advantage. In these days the problem of utilizing *time advantageously* is becoming a more and more difficult one, and those who learn early in life how not to waste the hours at their disposal have taken a most important step in achieving such success as lies within their reach.

Conclusions

In the course of these rather desultory and disjointed remarks no attempt has been made to lay down hard-and-fast regulations governing the prescription of work, rest, or play for the preservation of health or for combating disease. No prescription of the kind can be printed and distributed indiscriminately to all who seek advice on this subject, and no rules can be formulated, applicable to any case, without careful consideration of the individual and personal factors involved.

But if regulations are impossible guiding principles are not without their value, and among these I would emphasize again:

(*a*) The recognition of work as an ally, not an enemy, in *therapeutic operations on nervous disease.*

(*b*) The paramount importance of a correct diagnosis in functional disorders before determining the part to be played by rest and work in their treatment.

(*c*) The value of physiological and psychological considerations in the choice of recreations.

The subjects to which I have directed your attention, if they are not altogether commonplace, at any rate pertain to everyday life. The questions I have raised are among those which every individual believes he is best fitted to decide for himself. They certainly *do not admit of* dogmatic answers, and I shall be well content if they stimulate serious consideration, and suggest habits and prescriptions of work, rest, and play such as will promote health and prevent disease.

THE PROBLEMS OF MELANOMA*

BY

PROFESSOR JAMES EWING, M.D.

(*From the Pathological Department of the Memorial Hospital, New York.*)

The problems of melanoma maintain their position as the most interesting and complex of any department of oncology. Numerous competent investigations of the past decade, especially those of Dawson[1] and of Masson,[2] while illuminating some questions, have left others quite untouched or even more conspicuous and uncertain. The complexity of the sensory nerve endings, the peculiar relations between these structures and the cutaneous epithelium, the wide distribution of chromatophores, and the ramification of the whole subject of pigment formation in the animal kingdom render the study of melanoma quite a different matter from that of any other malignant tumour process. It is the object of this communication to enumerate some of these problems, not with the ambition of presenting a solution, but with the hope that a simple statement of them may lead to more *definite efforts toward* a solution as the progress of knowledge permits. Tumour pathologists may not feel flattered that the discovery of the nervous origin of the nævus, made by Soldan[3] in 1899, remained practically unnoticed until it was rediscovered and elaborated by Masson in 1927. Possibly there are other important data lying within easy reach of the alert observer.

Origin of the Quiescent Nævus Cell

Since the work of Soldan, and especially after the more elaborate and complete exposition of Masson, there is no longer any room for debate about the *nervous origin* of the nævus cell. In the so-called 'nerve nævus,' occurring mainly in the subcutaneous tissue, but often quite superficial, Masson has shown that the nævus cell is a derivative of specialized cells in the sensory nerve endings. In and about the groups of small glassy quiescent nævus cells he finds many nerve fibrils, and in many cases of nerve nævus these cells are aggregated into definite end organs of the type of Meissner's corpuscles, and in such intimate relation to the nerve fibre bundles as to leave no doubt that they belong to the peripheral nervous system. Every transition from the nerve end-organ with a ring of polyhedral cells up to the characteristic groups of pure nævus cells can be followed in these nerve nævi, while the epidermis fails to show the slightest sign of abnormality. It is remarkable that this fact could so long escape recognition, even after the simplest histological technique.

Masson does not undertake to decide whether the nævus cells are mesodermal, glial, or epidermal, but insists that they belong to the nerve end-organ. The relation to the chromatophore remains unaffected by this observation. The cells of the Meissner corpuscle are unpigmented, but a mantle of chromatophores often covers the peripheral rim of the nævus. *In some cases the two orders of cells,* pigmented and unpigmented, appear to be entirely separate, but in other cases the more peripheral cell groups show increasing pigmentation. These features strongly indicate that the special cells in the nerve nævus produce the pigment.

All these recent studies seem to dispose finally of the theory, first advanced by Unna, that the nævus cell is a *displaced down-wandering epithelial cell,* or that it is an endothelial cell, because of its endothelial morphology. There has never been any substantial basis for either of these time-honoured misconceptions. They do not, however, dispose of the possible participation of epithelium in some of the manifestations of melanoma or of the general class of pigmented tumours.

Unna originally, Nicholson, Dawson, and many others, have described in detail what they *regarded* as the down-wandering of pigmented nævus cells from the epithelial layer and their depigmentation when originally pigmented. I believe that these observations were made upon active melanomas, where it is undoubtedly possible to trace the down-wandering of tumour cells, *but they fail entirely to* prove that these down-wandering cells ever assume the glassy appearance of quiescent nævus cells. The evidence points strongly to the conclusion that in the active nævus the glassy cells proliferate in the derma while at the same time certain cells of the Malpighian layer also *proliferate,* the two groups uniting and forming the complex picture of the growing melanoma with supposed epithelial invasion. *In most melanomas,* especially those derived from deep nævi, there is no participation whatever of the epithelial layer, but in some cases both types of cells, those of the Malpighian layer and those of the corium, are active.

It thus appears that melanoma involves a growth of the specific cells of the sensory nerve endings, nævus cells in the corium, and in other cases the tactile corpuscle of Merkel-Ranvier and the chromatophores in the epidermis. One can find much evidence favouring the view that the epidermal participation in melanoma does not *involve the* whole epithelial layer, but only the specialized cells of Merkel and the chromatophores. *These soon form* small groups that stand out prominently in the Malpighian layer and then invade the derma. These cells *are never* exactly like those of ordinary epidermoid carcinoma. They are finely granular and opaque. They *form* peculiar groups of crescentic or polyhedral cells, which the experienced histologist easily recognizes as melanotic, and they retain these characters in metastases.

The Tactile Corpuscle of Merkel-Ranvier

The nature and behaviour of the tactile corpuscle of Merkel-Ranvier still remain obscure, untouched by *recent studies, and continue* to present one of the fundamental questions. Merkel and Ranvier showed that the *terminal* filaments of the sensory nerves *arborize* about certain cells of epithelial morphology lying in the Malpighian layer of the skin. These cells do not appear to differ in *any* respect *from the average epithelial* cell of the skin, but their relation to the nerve filaments raises an assumption that they may be *of nervous origin,* and to that extent

* Paper read in opening a discussion in the Section of Bacteriology, Pathology, Dermatology, and Biochemistry at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

similar in nature to the naevus cells of the deeper nerve end-organs. It seems most improbable that the terminal nerve fibril should appropriate any ordinary epithelial cell for its physiological functions. A parallel example is the taste bud of the tongue where the nervous origin is probable. This question seems at present to be unsolvable, but there is considerable evidence suggesting that the tactile corpuscle is not an ordinary epithelial cell, and that it behaves independently in some of the manifestations of melanoma and other diseases of the skin.

In addition to the tactile corpuscle of Merkel-Ranvier there are in the epidermis of most subjects, or under many circumstances, wandering pigmented chromatophores which have an important relation to melanomas of the skin. Bloch has shown that in the unpigmented skin of the infant stained by the dopa method peculiar cells are found in which the pigment material is invisible under ordinary circumstances. Apparently the skin is prepared in the embryo to produce pigment from slumbering chromatophores when it is needed. There are thus two types of specialized cells in the epidermis—chromatophores and tactile cells—with relations to melanoma, and the question of the relation of these two types of cells remains unsolved. The conditions in the subcutaneous nerve naevus—nerve cells associated with chromatophores—seem to be duplicated in the epidermis. After careful study of several nerve naevi and many early melanomas I have been inclined to suspect that the wandering chromatophore of the epidermis bears the same relation to the tactile corpuscle as the pigmented cell of the deep nerve naevus bears to the unpigmented naevus cell. According to this view the naevus cell becomes transformed into the chromatophore. This theory is practically identical with Ribbert's[4] except that Ribbert was not aware of the nervous relations of the deep naevus cell. In offering this suggestion regarding the nature of the tactile corpuscle, I am fully aware that the evidence in its favour is quite inadequate. It may well be that the tactile corpuscle is an ordinary epithelial cell, and that the nerve fibrils end blindly in the epidermis.

Relation of Naevus Cell with Chromatophore

Recent studies do not offer a complete explanation of the origin and relations of the chromatophore. Comparative studies of the pigment function in the animal kingdom strongly favour the belief that the chromatophore is a specialized cell not to be identified with any other cell type derived originally from the mesoblast and with important relations to the nervous system. Yet the evidence from human pathology is against this exclusive theory. Stockard's[5] study of pigment cells in batrachians indicated that these cells arise very early in the embryo and ovum from mesoblastic tissue and that they maintain their identity throughout the life of the animal. In vertebrates pigment production is evidently more complex.

The indications from comparative pathology are so strong that I have always agreed with Ribbert that one should maintain the theory of the independent nature of the chromatophore against all but the most convincing evidence. The relations to the nervous system are very prominent. In the chameleon this cell is attached to the sympathetic nerve fibril and supplied with contractile muscle fibres which control the colour changes in this animal. The wide-wandering function of the chromatophore in lower animal and man is noteworthy. This cell accompanies the ramifications of the sensory and sympathetic nerve fibres in many situations. It is widely distributed in the meninges of many subjects where its freedom from epithelial relations becomes most obvious. In the adrenal the pigmented cells are of neuro-ectodermal origin, but it is not clear that these cells have any close relations with the chromatophores of the skin, choroid or true melanoma. In the skin and choroid it obviously functions as a protection against light. All these features point to a special origin and physiology for the chromatophore.

Additional evidence regarding the nervous relations of the chromatophore is furnished by Masson's study of naevi. In the deep naevi the chromatophores appear in most lesions as satellites about the proliferating unpigmented naevus cells which are derived from the sensory nerve end-organs. From the study of several nerve naevi I find every transitional stage between unpigmented naevus cells and pigmented cells, and have been forced to the conclusion that the chromatophore in this case is derived from the naevus cell. This view accords with the conclusion of Ribbert that the chromatophore bears the same relation to the naevus cell as the glia cell does to the ependymal cells. While many deep naevi are free from pigment in many others pigment begins to appear in the periphery of the lesion and sometimes in the epidermis, and in such cases the whole series of naevus and pigmented cells is entirely separated from any epithelial connexions.

An origin from naevus cells does not fully identify chromatophores with naevus cells. Having once been derived from their cells of origin, they seem to acquire new properties and to function in many respects independently. Moreover there may be many other situations in the development and physiology of the nervous system leading to the formation of chromatophores. It is not necessary to assume that all chromatophores develop in the course of nerve naevi, which is a pathological lesion of the general character of a haematoma and prone to develop tumour processes. That some melanomas are derived from adult chromatophores without any intervention in naevus cells seems probable, this will be discussed shortly.

Some forms of abnormal pigmentation of the skin, due to activity of chromatophores, and the diffuse deposits of chromatophores in the meninges, seem to show that adult chromatophores enjoy an independent existence apart from any connexion with naevus cells, from which they are developed in many melanomas.

Present indications therefore, point to the conclusion that naevus cells and chromatophores are different phases of the same cell order, and that both are derived from the nervous system and are free from any epithelial entanglements. Most of the facts about melanoma seem consistent with this theory, including the structure of the nerve naevus, the appearance of intra-epidermal melanomas, the occurrence of pigmented and unpigmented tumours often in the same subject, and the ready assumption of pigment production in non-pigmented melanomas.

Epithelial Origin of Melanoma

The epithelial theory has enjoyed great popularity in the past, but since the demonstration of the neural origin of naevus cells it has lost its main support. There remains, however, very substantial histological evidence that in many melanomas certain cells of the Malpighian layer participate in the process. In many cases the whole Malpighian layer becomes riddled with small, peculiar cell groups, pigmented or not, the basal cells seem to proliferate, and the rete columns dip down into the derma, become elongated and mingled with other cells of the deeper portion of the tumour, giving the impression that the whole process is mainly epithelial. It is this process which Dawson and many others have so fully depicted, and it has hardly escaped the eye of any experienced pathologist.

In this complex field I do not think that positive statements can safely be made because the histological interpretations are so difficult and uncertain, but there are several considerations which the adherents to the epithelial theory must consider and dispose of before the epithelial origin of any cutaneous melanoma can be adopted even as a partial explanation.

1. There are undoubtedly pigmented epithelial tumours of the skin which have nothing to do with melanoma and it is sometimes difficult to distinguish between them. These are the pigmented epithelial papillomas, pigmented basal cell tumours, pigmented carcinomas in xeroderma pigmentosum. Chromatophores are generally present in these lesions often in considerable numbers. In these pigmented epithelial tumours the pigment is sometimes produced by chromatophores, which accompany the growth of epithelium but do not exhibit any neoplastic quality. When the tumours are heavily pigmented there seems to be no doubt that the epithelial cells may take on

the function of pigment formation This fact does not make them true melanomas, but it may be difficult to distinguish them from melanoma Especially in a group of basal cell tumours of the skin, in which the cells are very small and the pigment abundant, the separation from melanoma requires very careful histological study and clinical observation of the course of the disease Such tumours have no bearing on the questions of true melanoma It should be noted that in these true pigmented epitheliomas the growth affects the entire layer of the epidermis, and not small isolated groups of cells, so that the whole picture is quite different from that of melanoma

2 When epithelium appears to take part in the formation of a true melanoma the appearances are peculiar and unlike any other early epithelioma Isolated cell groups appear throughout the Malpighian layer which are different from the ordinary epithelium It is possible that these cells develop from chromatophores, since many of them are pigmented, as in the infantile naevus, or they may possibly arise from tactile corpuscles, which may be of neural origin In any case, the appearance of such lesions is quite different from that of any ordinary epithelioma, and this raises a doubt as to the epithelial nature of the participating cells

3 The invasion of the epidermis by melanoma cells from below, or from the sides, produces pictures which are difficult to distinguish from the primary proliferation of Malpighian cells The same difficulty arises in Paget's disease of the nipple, in metastatic carcinoma of the skin, and in adenocarcinoma of the rectum In Paget's disease of the nipple the epidermis exhibits somewhat the same appearance of isolated cell groups infiltrating the Malpighian layer as appear in melanoma, and yet we know that these cells originate at a distance in the ducts of the nipple, and are not derived from the cells among which they are found

4 In the most characteristic cases of supposed melanocarcinoma of the skin I have been unable to convince myself that the ordinary epithelial cells actually take part in the dermal invasion, and I consider that it is sometimes impossible to decide this matter from simple histological examination In most of these cases the epithelial cells seem mechanically displaced downward, and are eventually lost among the proliferating chromatophores or naevus cells which constitute the true tumour cell I have not been able to find a single case where the participation of epithelial cells in a melanoma was unquestionable, but it must be admitted that in some instances it is difficult to exclude them

5 The peculiarities of the cells of melanocarcinoma throughout their entire course—which enable the pathologist to identify them as melanotic and not as simple epithelioma—suggest that the cells of origin are peculiar, and not truly epithelial

Since there is no doubt that true naevus cells or chromatophores participate in most of these melanomas in which epithelial growth appears to occur, we must face the peculiar situation that a homogeneous type of malignant tumour owes its origin to the malignant proliferation of two entirely different types of cells Here the epithelial theory of the origin of naevus cells finds an opening, but we have already seen that it is no longer tenable

All these considerations stand as warnings against the too hasty adoption of the epithelial nature of any true melanoma although they seem insufficient to exclude this theory Further evidence on the whole question seems necessary One additional fact comes from Ludlaw's silver impregnation method, which indicates that melanoma cells are silver-negative, while epithelium is silver-positive It may also be noted that Lund[6] cultivated in plasma the retinal epithelium and the choroid chromatophores, and found that the former grew in sheets like epithelium, while the latter grew out in threads or as isolated cells, like fibroblasts This observation has been confirmed by Smith[7]

Intra-epidermal Melanomas

Two histological types of melanomas arise within the Malpighian layer and remain within its limits for a variable period In one of these the cells are pigmented, and elongated or spindle in form, and resemble adult chromatophores In the other the cells are small, unpigmented, polyhedral, and reproduce almost exactly the types of growing naevus cells in dermal melanoma

Case I

A woman, aged 51 years, had on the back of the hand, which had been affected by poison ivy six months before, a small dark spot, which in the course of a few months became black and enlarged to 4 mm in diameter It was then excised Section showed a lesion entirely intra-epidermal The epithelial layer was broken up by the appearance of numerous groups of elongated pigmented cells, between which unpigmented atrophic epithelial cells could be detected The basal layer was ragged, and many of the basal cells seemed to be pigmented or else replaced by pigmented cells The pigmented growing cells lacked the form and opacity of the normal epithelium At the bases of some rete columns the normal epithelium was completely lost and was replaced by masses of quite long pigmented cells resembling adult chromatophores In the derma there were no changes

The lesion was composed exclusively of cells of the type of adult chromatophores It was unlike any known form of epithelioma It seemed impossible to decide by histological study whether the pigmented cells arose from epithelium or from chromatophores previously existing in the epidermis It closely resembled the process in Paget's disease of the nipple, except that the cells were pigmented and elongated On account of the general facts known regarding the presence of wandering chromatophores in the skin, I am inclined to think that the process involved only chromatophores, and that the epithelium was passive

Case II

This case dates from 1905, and no history is available The lesion consisted of a flat elevated circumscribed non pigmented tumour, 6 mm in diameter and 2 mm deep, lying entirely within the epidermis It was composed exclusively of rather small non pigmented polyhedral cells of the type of naevus cell, except that the cytoplasm was granular They were rather loosely aggregated In the centre of the lesion they had completely replaced the epithelium, with the exception of a thin crust of horny cells on the surface At the sides there was a sharp line of demarcation separating the tumour from the normal epithelium No transitions between tumour cells and epithelium could be traced at these points On the under surface the rete columns were enlarged and appeared distended by tumour cells, but not ruptured There was no invasion of the derma by any loose cells The derma itself was unchanged

Certain deductions seem warranted by the structure of these intradermal melanomas

1 The epidermis contains elements which are capable of producing both adult chromatophores and non-pigmented cells, closely resembling the growing cells of the deep naevus

2 The derivation of neither of these cells from epithelium is demonstrable in the lesions by transition stages, and the process is very different from that of any epithelioma of the skin

3 The appearances are consistent with the derivation of the tumour cells from specialized elements in the epidermis, which we know are connected with the sensory nerve-end apparatus, chromatophores, and tactile corpuscles

4 The possible derivation from epithelium *cannot* be excluded on histological evidence, and must be decided for or against on *the general knowledge of the factors entering* into the problem

On account of the general evidence supporting the view that naevus cells and chromatophores belong to the nerve endings, I am inclined to believe that the intradermal melanoma tells against the epithelial origin of melanoma, but I do not find the evidence conclusive

Derivation from Chromatophores

Having assumed that the chromatophore enjoys an independent existence *apart from any neural cell from* which it may be originally derived, it is interesting to inquire whether there are any pure tumours of once adult chromatophores, apart from naevus cells

Ribbert assumed that all melanomas were derived from chromatophores, and the *unpigmented* naevus cells as well It now appears more probable that the naevus cell produces the chromatophore, while the reverse process is uncertain It seems to me very probable that certain melanomas are

derived exclusively from adult chromatophores but it is extremely difficult to separate these pure chromatophoromas from pigmented tumours of deep naevi and from superficial melanoma, *in which certain cells of the Malpighian layer probably take part*

The heavily pigmented tumours of the choroid are probably derived from adult chromatophores, but some of them in choroid iris and ciliary body have been traced to unpigmented cell groups which resemble the simple naevus In the skin both in the Malpighian layer and in the derma one encounters heavily pigmented tumour *which seem to be composed exclusively of polyhedral and* spindle-shaped chromatophores without the appearance of any naevus cells

In the meninges there are rare cases of heavily pigmented tumours for which there is little reason to assume any other origin than the adult wandering chromatophore Here an epithelial origin is satisfactorily excluded Yet some of these meningeal tumours gave secondary tumours which were unpigmented indicating that the chromatophore may produce an unpigmented cell in its tumour processes

Heavy pigmentation the tendency to produce long spindle cells abundant vascular supply and metastases exclusively through the blood vessels seem to be characteristic of pure chromatophoromas Yet this whole subject is very complex, and positive statements seem at present unwarranted

Relation of Melanoma to Neurofibromatosis

The observations of Masson establishing the neural origin of naevus cells confirm the numerous clinical and anatomical data that relate melanoma to neurofibromatosis One may now proceed with more confidence in accepting these indications that melanomatosis is a phase of neurofibromatosis

In many cases of neurofibromatosis there is diffuse pigmentation of the skin due to accumulation of chromatophores in the epidermis and derma and often marked by increase of pigment in the basal cells

In the average case of melanoma the signs of neurofibromatosis are not pronounced but when the naevi or melanomas become multiple or extensive then the deep naevi and cutaneous and subcutaneous neurofibromas are generally present Especially in the bathing trunk type of naevus the nerve trunks of the skin are apt to be the seat of multiple neuromas and fibromas and visceral neurofibromas are not uncommon

A charting of the location of several hundred melanomas by Pack shows a very general distribution but occasional cases in which the multiple tumours occur along the course of cutaneous nerves Pack's study also shows that melanomatosis is in general a rather late manifestation of neurofibromatosis The hereditary character of the two maladies is apparent when careful family histories are obtained but appears rather more marked in other types of neurofibromatosis Some remarkable cases of melanoma with neurofibromatosis have recently come under observation at the Memorial Hospital

In a young adult male the entire trunk was covered by a thick warty hairy bathing trunk naevus and both arms and leg exhibited many large and small lesions In most of these areas there were small cutaneous fibromas and a few subcutaneous tumours of nerve trunks Malignant melanomas developed in several areas and proved fatal with the usual course Excised area of the skin showed areas of diffuse neurofibroma and neuromas resembling nerve naevi and on the outskirts of these tumours groups of naevus cells and clusters of pigmented chromatophores were found The epidermis was generally intact

It seems very probable that careful search for indications of naevus formation and melanoma in neurofibromatosis and for signs of neurofibromatosis in cases of ordinary melanoma will be rewarded with important results tending to establish a close relation between these two diseases

The observations already available seem to furnish further substantial evidence in favour of the neural origin of melanoma and are difficult to reconcile with the epithelial theory

Nevertheless I would here record a remarkable case of pigmented epithelial papilloma with extensive black papillary tumours covering much of the trunk on one side of the body only, showing a characteristic segmental distribution on the trunk and a linear extension along the entire ulnar nerve On section, this tumour, contrary to clinical expectations, proved to be a simple very cellular, benign epithelial papilloma without any features of melanoma except abundance of wandering chromatophores Yet the distribution of the lesions and their gross appearance was exactly like that of the bathing trunk type of pigmented naevus

Relation of Trauma to Melanoma

The demonstration that the skin and subcutaneous tissue contain a complex nerve-end apparatus capable of giving rise to naevi and melanomas furnishes an explanation of the occurrence of some of these tumours following trauma, even when no pigmented mole existed in the affected area It may also account for the occurrence of melanomas in peculiar situations such as the bed of the nails about the anus, and in the mucous membranes In all these situations the tactile sense is highly developed and specialized nerve endings may be assumed to exist

While the nerve naevus is a pathological condition Meissner's corpuscles, from which they originate, are normal structures which probably have a wide distribution

With this knowledge the occurrence of a pigmented tumour following trauma in apparently normal skin becomes explicable since the trauma may affect one of these nerve endings or nerve naevi Such traumatic melanomas are especially frequent on the soles of the feet, but they have been observed in many other parts of the body and they occur at all ages In a recently observed case a projecting nail in the sole of a shoe penetrated the skin of the foot resulting shortly in a pigmented melanoma In another case in a young boy a contusion of the skin of the hand was attributed to bruising from catching a cricket ball, but it soon revealed itself as a non pigmented melanoma The frequency of subungual melanomas suggests a search in this location for some peculiar nerve ending which may explain the tumour growth

In medico-legal circles and especially in the compensation courts, there are indefinite reports of cases of generalized melanosarcoma supposed to have resulted from injury of skin or musculature or bones, or internal organs I have encountered several of these cases without being able to find satisfactory evidence that the melanoma resulted from the injury but also without being able to explain fully the conditions found

Case I

An adult apparently healthy labouring man received a wound of the hand which resulted in a severe palmar cellulitis The hand was incised on three occasions and pus evacuated After six weeks stay in the hospital he was discharged with the hand healed and in fair condition At no time was there any local sign of melanoma or any tumour process yet the patient did not recover his health, but went downhill steadily with abdominal symptoms and anaemia and died within six months after the injury Autopsy disclosed general melanosarcoma of the liver and abdominal lymph nodes but no primary focus of melanoma was discovered

In this case it is obvious that no conclusions can be drawn because of the lack of detailed evidence regarding the tissues of the hand and the possible existence of *primary melanoma in some occult location*

Case II

A young man aged 35 years a farmer was carrying a plank under his arm when he fell bruising the skin of the chest and axilla against the plank His previous health was alleged to be good The physician who first saw him after the accident and the operating surgeon failed to find any mole or tumour of the injured skin Within two weeks the lymph nodes of the axilla began to swell and soon reached the dimension of an orange The excised nodes showed a very cellular large-cell malignant tumour with characteristic *features of non-pigmented melanoma* The skin was involved in the process but never developed any tumour resembling a cutaneous melanoma. The patient succumbed to pleural and pulmonary extension

Here the evidence regarding the previous health of the patient the condition of the skin of the injured area and the exact histological type of the tumour is all defective

While the evidence in these and many similar cases is incomplete—and it seems probable that the melanoma is a coincidence—yet it raises a suspicion that the development of melanoma may not always be limited to superficial cutaneous or subcutaneous structures. Very complete studies of such cases are required before they can be accepted as instances of melanoma of traumatic origin. They suggest a search for structures of the type of naevi capable of giving rise to melanoma from the deep nerve fibres in subcutaneous tissues, lymph nodes, mucous membranes, and viscera.

Summary

1. The work of Soldan and of Masson has proved beyond a reasonable doubt that the naevus cell is derived from and belongs to the peripheral sensory nerve end organs. Whether this cell is *neuro-ectodermal or mesoblastic* is uncertain but an epidermal origin seems to be excluded.

2. The naevus cell in the nerve naevus produces chromatophores and the two types of cells are more or less interchangeable. Yet the adult chromatophore seems to enjoy a more or less independent existence and function apart from naevus cells. Whether there are other sources of chromatophores is uncertain but improbable.

3. In the epidermis there are slumbering, unpigmented and wandering pigmented chromatophores and probably also other specialized cells similar to naevus cells belonging to the intradermal nerve end apparatus. These latter cells may be the tactile corpuscles of Merkel-Ranvier. The conditions in the epidermis may therefore duplicate those found in the derma.

4. In the development of melanoma exactly the same processes seem to occur and the same relations between naevus cells and chromatophores seem to be exhibited in the epidermis as in the nerve naevus of the derma and subcutaneous tissue.

5. The theory of the epithelial origin of the naevus cell and chromatophore has always been seriously questioned by most pathologists and in the light of the new evidence has become less acceptable. All the appearances in the epidermis suggesting the active participation of epithelium in melanoma may be referred to the growth of specialized cells belonging to the nerve end apparatus. Yet the histological evidence in this field is complex and inconclusive.

6. Melanoma has important relations to neurofibromatosis. This fact supports the view that the cells in melanoma are of neural origin and it is difficult to reconcile with the epithelial theory.

THE CLINICAL ASPECT OF DISTURBANCES OF THE PARATHYROID GLAND*

BY

J. C. MEAKINS, LL.D.Ed., M.D., F.R.C.P.Ed.,

DIRECTOR, DEPARTMENT OF MEDICINE, MCGILL UNIVERSITY

It may be stated briefly that the function of the parathyroid glands is the maintenance of the calcium content of the blood plasma at a definite level and the control of the calcium balance of the body. It would also appear that these glands have an important function in regulating the calcium metabolism of the fixed tissues, particularly the osseous system.

For some twenty-five years the absence or deficiency of the parathyroid function has been identified with a lowering of the blood plasma calcium and the associated occurrence of increased electrical excitability of the neuromuscular system, producing the well-known clinical picture of spasmodic tetany. But it has been only in comparatively recent years that clinical biochemical and pathological studies have enlarged our horizon and associated other abnormal conditions with disturbances of the parathyroid function. I think it may be taken that *theoretically* this function might be disturbed in one of three ways, as follows. There might be either (1) a decrease in the normal function, (2) an increase in the normal function or (3) a perversion of this function. As far as is known at the present time no such condition as would occur under the third category has been recognized as such. There are therefore left for consideration such conditions as might be identified under the first two sections. It might serve a useful purpose to consider at this time what conditions might be caused by a derangement of parathyroid function and then determine if such an association is tenable on known facts.

On what basis or criterion may it be tentatively assumed that a disturbance of parathyroid function might exist? The function of the parathyroid has already been defined. There could therefore be no better tentative criterion than such as would indicate a disturbance of this normal function of calcium regulation. In the table are given the various disease conditions which are associated with a disturbance of the calcium metabolism. There has been included a record of the phosphorus content of the blood as the calcium and phosphorus metabolism is so intimately associated that frequently it is impossible to interpret the significance of the first without a knowledge of the second. Of the six conditions there is definite knowledge that 1 and 6 ("parathyroid tetany" and osteitis fibrosa) are intimately connected with abnormal function of the parathyroid glands.

No.	Disease	Blood Calcium	Blood Phosphorus	Calcium Balance	Bony Changes
1	Parathyroid tetany	Low	Normal or increased	Positive	None
2	Nephrosis	Low	Normal	Positive	None
3	Steatorrhœa with megalocolon (sprue coeliac disease)	Low	Normal	?	None
4	Rickets—infantile	Low usually	Low sometimes	Relatively negative	Present.
5	Osteomalacia	Decreased normal or increased	Variable	Negative	Present
6	General osteitis fibrosa	High	Low	Negative	Present

"Parathyroid tetany" is a condition which occurs subsequent to removal of the parathyroid glands or to their injury or degeneration from some other abnormal cause. It is characterized by increased mechanical or electrical excitability of the neuromuscular system with muscular hypertonicity leading to painful spasmodic contractions of the muscles of the limbs, trunk, and certain internal muscles such as those of the larynx, diaphragm, bladder, and bowel. There is also a pronounced decrease of the calcium content of the blood, which is usually in proportion to the degree of muscular irritability. There is little or no change in the *pH* of the plasma. This syndrome may be either permanent or temporary. In the former case it may lead to a painful death unless corrected by the constant use of parathyroid extract. On the other hand, it may be but temporary disappearing completely, or being latent with but mild and temporary manifestations. Tetany is a syndrome, however, which may occur with any condition where there is a low blood calcium, or even a normal blood calcium with a prolonged negative balance, provided the *pH* of the blood and its phosphorus content be not conspicuously lowered. Such conditions are to be found in steatorrhœa with megalocolon, infantile rickets, and osteomalacia, in all of which there is a low calcium content of the blood and either absolute or a relative negative calcium balance. But the mere occurrence of tetany does not necessarily imply that the pathological condition is primarily due to a deficiency of parathyroid function. In fact there is no evidence, either experimental or clinical, to warrant such an assumption, except such as may be concluded from the fact that both in rickets and in steatorrhœa with megalocolon, or what is sometimes

* A paper read in the Section of Bacteriology, Pathology, Physiology and Biochemistry at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

called 'non-tropical sprue" the administration of parathyroid extract, with or without an abnormal increase of calcium in the diet, relieves the symptoms of tetany by raising the level of the blood calcium There are, however other means whereby this may be accomplished in rickets although in non-tropical sprue the most efficient method of treatment is undoubtedly the use of parathyroid extract, not only in controlling the paroxysms of tetany but also in ameliorating the intensity of the gastro-intestinal signs and symptoms In fact, cases have been reported in which it would appear that a permanent cure had been effected by this means In osteomalacia the effect of parathyroid therapy has not as yet been determined but its close relationship to infantile rickets would appear to indicate that this form of therapy might be fruitful of beneficial results

In the last five years a considerable interest has been aroused in the relationship of parathyroid tumours to diseases of the bone In 1891 Recklinghausen described a generalized osteitis fibrosa, a disease which now bears his name This pathological condition was more intensely studied by Askanazy in 1904 The first to draw attention to the association of parathyroid tumours and bone disease was Erdheim in 1907, in which connexion he described a parathyroid tumour associated with osteomalacia Hoffheinz in 1925 in a series of 45 cases with parathyroid tumours either hyperplasia or adenoma, found 27 with diseases of the bone 17 of which were classified as generalized osteitis fibrosa 8 so-called osteomalacia and 2 rickets In the same year Mandl reported a similar case and in 1927 Gold reported another Mandl found a great increase in the calcium excretion, while Cold *described an increase in the blood calcium* This subject has recently been reviewed by Hunter in his second Goulstonian Lecture He here records that 14 carefully studied cases have been published up to date giving the clinical characteristics of hyperparathyroidism These characteristics are briefly as follows Whether the disease be due to a tumour a hyperplasia of the parathyroid or whether these glands be found normal histologically the condition occurs twice as commonly in women as in men and generally between the ages of 30 and 55 The patients complain of pains in the bones and spontaneous fractures are common Hypotonicity of the muscles is sometimes present and radiograms show a greatly diminished density of the bone shadows at times with evidence of cystic formation There is an increased serum calcium varying from 13 to 23 mg per 100 c cm a reduction in the plasma phosphorus to between 1 and 2 7 mg, and in all cases there is *an increase of the calcium output which may vary from* a moderate degree to eight time the normal figure It would appear, therefore as if this condition were the opposite to that found in parathyroid tetany except that there is the additional anatomical finding of pronounced bone destruction

The superficial similarity of generalized osteitis fibrosa and osteomalacia has led to considerable confusion in the study of this subject Hunter brings forward argument which would seem conclusive to warrant the opinion that these are entirely different diseases Furthermore the general course and accessory clinical manifestations such as tetany which occurs in osteomalacia would make it much more likely that it is a disease more closely allied to infantile rickets than it is to the hyperparathyroid condition so intimately connected with generalized osteitis fibrosa

Nephrosis is an interesting condition which would appear, in part at least, to be a disturbance of the permeability of the capillaries This is manifested by an intense degree of albuminuria and generalized oedema There are in addition two interesting disturbances of metabolism one or other of which is usually present—namely decreased basal oxygen consumption and or a lowered blood calcium The chief interest in this disease which shows such pronounced renal factors rests in the fact that a marked lowering of the blood calcium is present in a considerable number of cases and that some of them respond most favourably to *the use of parathyroid extract not only in so* far as the restitution of the blood calcium is concerned, but also in promoting a rapid disappearance of the generalized anasarca As has been said concerning numbers 3 4 and 5 in the table so it may be said in regard to this disease that although there be a disturbance of the calcium metabolism which may be rectified by parathyroid extract there is no concrete evidence that the disease is primarily due to a deficiency of the parathyroid function It is interesting to note in this instance that, although the serum calcium is reduced there is never in these cases any suggestion of neuro-muscular hyperexcitability or tetany The explanation is probably to be found in the tendency in these cases of the reaction of the blood to be toward a decreased *p*H

In conclusion we may state that clinically two conditions are identifiable with disturbed parathyroid function, *the first being parathyroid tetany due to a hypoparathyroidism* characterized by a low serum calcium a positive calcium balance, and great hypertonicity and excitability of the neuro-muscular system On the contrary, there is generalized osteitis fibrosa a condition of hyperparathyroidism in which there is a high serum calcium a negative calcium balance and a tendency to hypertonicity and hypo-excitability of the neuro-muscular system, a pronounced rarefaction of the bones and a resorption of the corticalis and original spongiosa this being in striking distinction to the cessation of calcification characteristic of osteomalacia and rickets

ALBUMINURIA OF PREGNANCY AND ITS LATE RESULTS*

BY

J B BAINSTER M D, F R C S Ed, F.R C P,

CONSULTING OBSTETRIC PHYSICIAN QUEEN CHARLOTTE'S HOSPITAL
OBSTETRIC PHYSICIAN CHARING CROSS HOSPITAL.

THE presence of albumin in the urine during pregnancy and labour may be fairly regarded as the commonest abnormality during these states On reviewing some 6 000 cases *in which there has been a complete routine examination*, it is found that about 30 per cent of all patients exhibit this abnormal urinary constituent About seven-eighth of these only show albumin in the urine during the labour itself and its presence may be regarded simply as the expression of severe muscular effort therefore for clinical purposes this type of case may be disregarded The remaining examples of the phenomenon mainly occur during pregnancy, and it has been my endeavour to ascertain as to what extent this abnormal condition influences the subsequent history of an individual

It is necessary to say at the outset that when we try to formulate an answer to this question we soon become impressed by the futility of the effort In the first place we are struck by the absence of statistics bearing upon this point It is only during the past few years that at any rate in England any attempt has been made to learn the subsequent history of patients who have suffered from this complication As an example of the paucity of records, it is only necessary for me to say that in answer to my requests for help I have received from one hospital a statement that their records are in a condition of complete chaos and from another that there are no records whatever bearing on this point I think this sufficient to suggest that there is great need for more careful compilation of statistics in maternity institutions The more for a unification of method in preparing clinical reports of maternity institutions should be productive of much good in this direction especially if attention be focused on this class of case It would of course be necessary to collate all detail of the subsequent histories of albuminurics both as regard the course of future pregnancy and the general health Moreover, such investigations to be of material assistance should be extended over a period of at least five years from the date of the initial illness We must also remember that the statistics

* Read in opening a discussion in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, Winnipeg 1930.

of maternity institutions do not represent the true state of affairs, as they only take account of those cases which return to the same hospital for subsequent pregnancies. There may be a considerable number of patients who show, for example, a recurrent albuminuria, and who are looked after by some other institution during their later illnesses. There is no way of checking this save by meticulous care in collecting facts from the patients and by the collaboration of hospitals in verifying these facts. Lastly, any attempt to answer or consider this subject accurately ought to be carried out in consort with the medical departments of general hospitals. We as obstetricians, too often lose sight of our patients and it is the general physician who will undoubtedly be able to give us valuable help in trying to discover what may happen to an albuminuric in after-life. An analysis of the medical records of general hospitals would also help these investigations by providing evidence as to the rôle of albuminuria of pregnancy in the etiology of established nephritis as seen in the medical practice of those hospitals.

Any consideration of the late results of albuminuria of pregnancy must necessarily take into consideration the general condition of which that albuminuria is a symptom, and here we find another considerable difficulty—namely, that of classifying the various states in which this symptom occurs. Hospital records differ largely in their attention to this point and, indeed, I wonder whether any satisfactory classification can be made in the present state of our knowledge. In most records, the condition is regarded either as a transitory one or as one of the signs of pre-eclampsia or eclampsia or as an earnest of a chronic nephritic change. There is, of course, no doubt that the matter is not as simple as this. It is, I think, universally recognized that these clinical types do not always exist pure, and there is quite often a mixture of one or two in the same case. One might suggest with Dr. Stander, to whom is the credit of very helpful and careful work regarding all these conditions, that we might make the classification as follows:

1. Albumin present in cases of vomiting in pregnancy.
2. A clinical class of cases with "a low kidney reserve."
3. Frank nephritis complicating pregnancy.
4. That clinical condition which we know as "pre-eclampsia."
5. Eclampsia.

For the purposes of this discussion I propose to omit the vomiting of pregnancy entirely and to confine my efforts to formulating some idea as to the subsequent history of the four remaining groups. In deciding to which group a given case belongs I have had to rely upon the information obtained by reading the clinical history, and it is but seldom that I have found the condition proved by any biochemical or any other more elaborate means of investigation. I have known of cases in which the clinical condition is very widely different from that which has been foreshadowed by the laboratory investigations, and I am not very sure that this method is of any considerable help. The idea was widely held up to the last few years that an attack during pregnancy of a purely toxic nature (I use the word in full consciousness that we are as yet ignorant whether it be a toxæmia or not) tended to make the patient less subject to the condition in succeeding pregnancies. When we read the textbooks of obstetrics we find that it is usually stated that *an attack of severe albuminuria confers immunity upon the sufferer, and that subsequent pregnancies will take place without any untoward symptoms.*

The painstaking work of Stander, James Young, Gibberd, and others has given us furiously to think. Young, for example, states that out of forty-seven cases of eclampsia there were six—that is, 12·8 per cent.—in which signs occurred in a previous pregnancy, and in nine cases there was a toxic condition in a subsequent pregnancy which did not reach the convulsive stage. This gives a recurrence of 31·9 per cent. These findings have been corroborated in the work which he has carried out since the paper in which these figures are quoted. Gibberd finds a recurrence rate of nearly 40 per cent., and much the same conclusions have been reached by Harris of the Johns Hopkins Hospital. I have tried to investigate as many cases as possible in order to be able to formulate some ideas in this respect, but as I said at the outset, the matter is one of very considerable difficulty.

We have to answer, if possible, the following questions:

1. When a patient develops a mild albuminuria in pregnancy, with perhaps a light oedema with no marked rise of blood pressure, and a generally unimpaired state of health, is she likely to show in future years or in future pregnancies, any evidence that her kidney has been permanently damaged?
2. Is a patient who suffers from chronic nephritis likely to display a progressive deterioration of kidney function in future pregnancies?
3. Is a patient who has been the subject of a true eclampsia or a pre-eclampsia likely to suffer in a similar manner should he become pregnant again?
4. Does the toxic albuminuria of pregnancy play an important part in the etiology of chronic nephritis?

My own experience is confined to some 60,000 cases of labour. It is large enough to know that anything may happen to these patients, but it is far too small to be able to forecast what is most likely to happen. I have therefore endeavoured to obtain help from various other sources, and this I have received from Professor Louise McIlroy who has given me the results of the recent experiences of the Royal Free Hospital Obstetrical Unit, and I have also to acknowledge the great assistance I have received from my registrar at Charing Cross Hospital, Dr. Dodds, who has very kindly examined the clinical records of the City of London Maternity Hospital in order to try to find some data bearing on the subject of this discussion. I must here express my gratitude to both these doctors and also to the staff of the City of London Maternity Hospital in allowing my registrar to use their records.

In all, nearly 30,000 cases of labour have been examined, and of that number 1,700 exhibited a condition of albuminuria which necessitated treatment during pregnancy.

There are among this number eighty-six cases in which the albuminuria has recurred more or less severely in subsequent pregnancies. This is a much lower percentage of recurrence than that found by previous observers, but I imagine that, were the histories more complete, we should find a greater number of recurrent cases.

In going over the histories of these eighty-odd patients one cannot help being struck by their extraordinary diversity. For example, out of my own practice I have notes of two patients, one of whom had a very severe eclampsia with her first baby and showed the presence of albumin for eighteen months afterwards. She then became pregnant again, and at the third month this albumin completely disappeared, and has not been found again throughout her two subsequent pregnancies and labours. Another who had a very severe eclampsia, for which I did a Cæsarean section (this was some years ago), has never from the time that the baby was 1 week old had a trace of albumin in the urine, although she has had three other children. On the other hand, I have notes of a patient who had an eclampsia in her first pregnancy, became pregnant again after two years, and albumin appeared in the urine at the second month, accompanied by a rather high systolic blood pressure (190). She was treated for some time according to the ideas prevailing at the moment, but she died in what I have no doubt was an attack of uræmic coma in the fifth month of this second pregnancy. There are also notes of patients who had had a pre-eclampsia for the first and third pregnancies, while the second was entirely normal, and there are records of albuminuria in succeeding pregnancies as far as the seventh, and then the eighth and ninth are recorded as being normal. Such instances, taken haphazard from these collected cases, are sufficient to demonstrate to you that I am unable to give any precise answer to the questions I have set. All I can give you are certain general conclusions based on the analysis of these eighty-six cases.

The first question is, from my experience, to be answered in the negative. Those cases which may be accounted

examples of a low kidney reserve do not I think tend to show further manifestation of a like nature in subsequent pregnancies The consideration of the case under review bears out this conclusion

The answer to the second question is in the affirmative It the condition of chronic nephritis can definitely be established it is I think certain that the kidney will show a progressive deterioration in subsequent possible pregnancy As Cribbend says Pregnancy is the most delicate test of renal efficiency" and I think it is abundantly true that the kidney in this class of case is increasingly unable to stand this test

It is the answer to the third question which is of most practical importance to us as obstetricians and unfortunately here I must confess that I cannot give any dogmatic pronouncement It is however abundantly clear that in about 30 per cent of cases there is a tendency toward either recurrence of the actual condition in subsequent pregnancies or towards some other complication of that pregnancy such as ante partum haemorrhage abortion or intrauterine death of the foetus in the later week

Certain clinical facts are to be noticed in studying my cases which I think may be of help in anticipating the course which a subsequent pregnancy may take

In the first place, there is the duration of the illness These cases suggest to me that an attack of pre-eclampsia or eclampsia of short duration is less likely to be repeated than one which has been spread over many weeks From this conclusion may be drawn the inference that these albuminuric cases should not, in the absence of signs denoting definite improvement, be subject to overlong treatment, but that termination of labour should be practised say after ten days

Secondly, there appears to be no doubt that the blood pressure bears as important a relation to future events as it does to a present condition In these cases which I have studied I find no case of recurrent albuminuria in which the systolic blood pressure during the initial attack was under 150 mm The changes in blood pressure after delivery are also important as I shall show in a moment for the next clinical fact of the case of albuminuria which is important in view of its prognostic value is the reaction to treatment One has found that most cases in which medical treatment is quickly followed by a general improvement and by a fall in blood pressure do not tend to recur should the patient become pregnant again In considering the history of the convalescence the following two points are abundantly clear First when the blood pressure remains constantly raised during this period we are dealing with a patient in whom we may reasonably expect symptoms during a subsequent pregnancy It is also I think true that a persistence of albumin over more than two to three months is a sign that pregnancy may be complicated by a similar state of affairs should it occur again

Perhaps I might digress a little from the actual consideration of the fate of albuminurics in regard to future pregnancies and for one moment suggest to you that the experience of these cases which have been followed through succeeding pregnancies enables one to make suggestions which I think you will find justified They are reflections on the prevention and management of these pre-eclamptic states First I would stress the importance of early recognition Any patient should be encouraged to report any untoward symptom and the attendant should be constantly on the watch for the early manifestation of this condition Secondly I would suggest the value of energetic and thorough treatment of the condition once it occurs We are too apt to regard the early signs of an albuminuria as no sufficiently important and I would recommend that all such patients should at once be placed under a strict regime of treatment Thirdly, they should not be treated too long as mentioned above I have an idea that this prolonged treatment defeats its object and leaves the patient more subject to recurrent attacks This leads me to the conclusion that when a time limit has been set say of seven days should recovery be not noted radical treatment should be chosen Though I cannot subscribe to the belief that eclampsia should be treated by Caesarean section, nevertheless I do believe there is scope for this operation in the severe toxaemias of recent origin

Turning from the consideration of the histories of these patients in recurring pregnancies, may I just draw your attention to the comparative commonness of mental symptoms after severe albuminuria occurring in pregnancy? My experience is that from 15 to 20 per cent of known eclamptics do exhibit a confusional mental state which may even extend to mania As a rule their recovery is complete and generally fairly rapid and I think any permanent mental instability is an expression of some pre-existing state and not a result of the toxaemia of pregnancy, though it is probable that the toxaemia has contributed to making the condition a permanent one

To the fourth question I can give no answer I do not know the etiological value of an albuminuria of pregnancy in the causation of chronic nephritis and for the elucidation of this point I think we must invoke the assistance of physicians

THE INTESTINAL ORIGIN OF ECLAMPSIA.

BY

R CHRISTIE BROWN, M B, M S, F R C S,

SURGEON TO OUT PATIENTS SAMARITAN HOSPITAL FOR WOMEN ASSISTANT OBSTETRIC SURGEON CITY OF LONDON MATERNITY HOSPITAL, AND JEWISH MATERNITY HOSPITAL.

THE purpose of this article is to offer an argument in favour of the intestinal origin of eclampsia of pregnancy

Eclampsia has been well named "the disease of theories" and like many other diseases around which an enormous literature has accumulated and for which many theories have been advanced, there is very little known about it All the pathological changes met with in this disease can be best explained on the assumption that a condition of toxaemia exists The composition and origin of the toxin are entirely unknown, but it seems logical—as eclampsia occurs only in pregnant women—to assume that it has its origin in the pregnant uterus arising either from the foetus or the placenta, most probably the placenta

For the present argument it is not necessary to deal minutely with the pathological changes, it is sufficient to state that similar changes occur in different organs—the kidneys, the liver the brain etc The changes found in the liver appear to be of chief importance in eclampsia Areas of haemorrhage and necrosis scattered throughout the liver are apparent to the naked eye, while the microscope reveals (1) Degeneration of hepatic cells, beginning at the periphery of the lobule and gradually spreading towards the centre of it so that in some cases the whole lobule is involved (2) Intertitial haemorrhages and areas of necrosis In nearly all cases of eclampsia the kidneys are similarly affected, small intertitial haemorrhages and areas of degeneration and necrosis are found in the cortex There is also a degeneration of the cell lining the convoluted tubules

It would appear that the toxin in the circulation affects various organs by producing areas of necrosis and small interstitial haemorrhages with consequent alteration in their normal functions Thus we find the kidney excreting albumin and no longer acting as an efficient barrier to the colloids of the blood Analogously the liver may also cease to act as a barrier between the portal and the systemic circulation, so that substances in the portal blood are allowed to pass unchanged into the systemic blood If this is so a condition exists in which a primary toxin of unknown origin damages the liver, with the result that substances from the portal blood are allowed to pass unchanged into the systemic circulation producing a secondary toxaemia which may be the origin of the fits In this connexion it is well to remember that it is the periphery of the liver lobule which is most affected the primary toxin probably being brought there by the hepatic artery and taking effect where it is most concentrated The portal venules are also around the periphery of the lobule and thus convey their blood directly to a damaged area of the liver which may be incapable of detoxicating its contents.

Of course, before any portal substances can penetrate the systemic stream, they have to pass normal cells in the centre of the lobule, but these cells represent only a small fraction of the whole as it is obviously mathematically correct that the cells in the periphery form the majority of the cells in the lobule

Among its many functions the liver acts as a detoxicator of poisonous substances absorbed from the intestinal canal via the portal vein Indole and phenol are examples of noxious substances carried by the portal vein they are products of protein decomposition and are formed in the large bowel by bacterial action on the amino acids tryptophane and tyrosine respectively These are detoxicated in the liver by oxidation and conjugation with sulphuric acid and pass on to the body, from which they are eliminated by normal kidneys most probably within twelve hours Indole is conjugated to indican, and consequently the proportion of indican in the urine forms a rough guide to the amount of putrefaction occurring in the large bowel Thus indican is present in large quantities in the urine of a patient suffering from intestinal obstruction but apart from such a grave lesion it is found almost invariably in the urine of constipated persons and can be made to disappear therefrom by purgation The amount of indican in the urine might serve as a guide to the functional capacity of the liver for dealing with portal toxins especially in subjects of constipation - a condition present in practically all pre-eclamptics or eclamptics In constipation we have every reason to believe that indole is passing via the portal vein to the liver which, if functioning correctly will convert it into indican and the latter substance will be detected in the urine If the liver fails to function no indican should be present in the urine The absence of indicanuria in a patient who is purged obviously has a different interpretation, and in eclampsia may be due to failure of the kidneys to excrete it

An interesting experiment was suggested by a Russian surgeon Eck and successfully carried out by Pavlov An artificial opening was made connecting the lumen of the portal vein with that of the vena cava in a dog The portal vein was then ligated above the anastomosis so that the blood passed directly into the systemic circulation without passing through the liver In some of the animals operated on in this way it was found that so long as their diet consisted only of carbohydrates they could be maintained in full health If they were given a large meal of meat many of them became ill and suffered from convulsions which ended in coma At the same time there was a large increase in the ammonia output of the urine This condition was supposed by Pavlov to be due to ammonaemia, the liver being regarded as protecting the body from ammonia produced in the intestine by converting it into urea In this condition—Eck's fistula—the speed and amount of conjugation of bodies such as indole and phenol is greatly reduced [1]

Slight injury to the liver by chloroform and phosphorus has little effect upon the phenol conjugation but extensive injury reduces it greatly Pelkan and Whipple[1] suggest that the fatal result of the Eck fistula experiment or even of chloroform poisoning may be due to the lack of conjugation of phenols It has been pointed out by Gibbon Fitz-Gibbon [2] and I have personally confirmed this in my own experience—that the eclamptic patient usually suffers from constipation and indulges in dietetic excesses Gibbon Fitz-Gibbon lays great stress upon the intestinal overload, and certainly the success of the Rotunda treatment (purges and high colonic washes) confirms this belief It is also interesting to note that the body weight of patients developing eclampsia increases more than the average [2] This abnormal increase would be expected in a patient who is overeating The seasonal variation, being highest in spring, could be explained also in this way, for in the months immediately preceding more meat and more food as a whole are consumed An eclamptic patient therefore appears to be in a suitable condition to suffer from intestinal toxaemia She is constipated and overeats, and her detoxicator—the liver—is damaged, which, on analogy with the kidney, may allow noxious substances from the portal vein to pass unchanged into the general circulation, causing a condition closely resembling that found in any animal upon which Eck's experiment has been performed In such a patient purging and colonic washes will obviously not only eliminate the primary toxin, but cut off the supply of the secondary toxin at its source

From what has been said above, it will be clear that one might expect eclamptic women even though constipated at the time, to exhibit either very little or no indicanuria, and this I have almost always found to be the case in the few eclamptics whom I have investigated in this manner

Summary

In cases of toxaemia of pregnancy there is present in the circulation a toxin (or toxins) of unknown origin which affects the cells of many organs, interfering with their normal functions The kidneys, if affected, no longer act as barriers to the passage of certain colloids from the blood into the urine Should the liver be affected, it may no longer detoxicate portal poisons, but allow either all or some of them to pass into the general circulation, introducing a secondary toxaemia which may be the cause of the convulsions

INCIDENCE OF THE SEROLOGICAL TYPES OF THE PNEUMOCOCCUS IN LOBAR PNEUMONIA

BY

J. M. ALSTON, M.B., M.R.C.P.Ed.

LECTURER IN BACTERIOLOGY, EDINBURGH UNIVERSITY,

AND

DONALD STEWART, M.D., M.R.C.P.Ed.,

ASSISTANT PHYSICIAN, EAST HOSPITAL, EDINBURGH; DAVIDSON RESEARCH FELLOW, EDINBURGH UNIVERSITY

(From the Bacteriological Department, University of Edinburgh)

The incidence of the different serological types of the pneumococcus in lobar pneumonia has been studied extensively during the past seventeen years, and the original classification of Dochez, Avery, Gillespie and others is now accepted by most bacteriologists In the present article, in addition to a note of recent observations on the incidence of these types in Edinburgh it is proposed to review briefly the findings of different observers during the past few years

By protection tests and the agglutination reaction with antisera Dochez and Gillespie were able to divide strains of the pneumococcus into four groups designated I, II, III, and IV Groups I, II and III were specifically differentiated in this way Group IV comprised heterogeneous strains which could not be identified immunologically with the other three groups Group III was also characterized by the possession of a thick mucoid capsule noticeable in the mucoid character of growths in culture media (*Pneumococcus mucosus*) More recently a number of constituent types referable to Group IV have also been identified by certain workers (Cooper, *et al*), but, as will be shown, in this country such further serological subdivision seems unnecessary from a practical standpoint, though it may be of importance in other countries The results of Dochez and Gillespie are noted in Table I

TABLE I.—*The Original Classification of Pneumococci by Dochez and Gillespie*

	Classification by Protection Tests		Classification by Agglutination Tests	
	No. of Cases	Per cent	No. of Cases	Per cent
Group I	28	45	22	41
Group II	12	20	11	0
Group III	9	14	9	17
Group IV	13	22	12	22

TABLE IV.—*Death Rate in Relation to Type Incidence, Edinburgh, 1929–30*

Type	No. of Cases	No. of Deaths	Death Rate (Percentage)
I	53	12	23
II	75	23	31
III	7	5	71
IV	47	5	10

It is to be observed that the order of severity is similar to that of other workers. The numbers, of course, are small, and may be insufficient for an exact statistical statement but it is interesting to note that the death rate in Group IV is as low as 10 per cent.

Summary

1. A brief review of the incidence of the different types of pneumococci in lobar pneumonia according to a number of observers from 1913 to date is given.

2. The incidence of pneumococcus types in 186 patients suffering from acute lobar pneumonia in Edinburgh during the past eighteen months is recorded, and also the mortality rates associated with the different types.

The authors gratefully acknowledge facilities granted to them by the physicians to the Royal Infirmary, Edinburgh, and thank Professor T. J. Mackie for valuable assistance. The expenses of this work were met in part by a grant from the Moray Fund, Edinburgh University. One of us (J. M. A.) was in receipt of a grant from the Medical Research Council.

A CASE OF OSTEOGENESIS IMPERFECTA

BY

J. F. WRIGHT, L.R.C.S.Ed.,

MEDICAL SUPERINTENDENT, HOLBERTON HOSPITAL, ANTIGUA

L. M., aged 34, a coloured woman, was admitted to the Holberton Hospital on July 3rd with a fracture of the left radius just below the insertion of the pronator teres and a fracture of the right olecranon. Both fractures were the result of direct violence—by being beaten with a walking-stick. She was unaware that the olecranon was fractured, and complained only of the left arm, which she knew was broken, and a contusion of the left leg. Her complaints of pain in view of pending legal proceedings were not very convincing, as she showed little sign of distress on manipulation. There was also a remarkable absence of swelling, ecchymosis, or muscular spasm.

Family History

The patient's father was a tailor who died of senile decay three years ago. He had had no serious illnesses or fractures. Her mother, whose legs were deformed, died some years ago, probably from pneumonia. The mother's sister, thought to be in America, also had deformed lower limbs. A sister and two brothers are normal.

Patient's History

The patient's mother told her that her legs were broken many times when a baby before she was old enough to feel pain, which seems to suggest that the pain was not of a degree usually associated with fractures even in an infant. Her first recollection was of a fractured femur which was followed by many fractures of the lower limbs up to the age of 16. These frequently occurred at school if she fell or was pushed about by other children. She stated that the fractures were painful, and used to swell.

According to the hospital records she was admitted in 1904, at the age of 7 with a fractured femur and was in hospital from May 2nd to June 13th. The following year she was again in hospital, from March 27th to May 23rd, with a fractured femur. In 1909 she was in hospital from February 19th to March 11th, the diagnosis being fragilitas ossium. On this occasion fractures were not specifically mentioned, but in view of the diagnosis and her good health in other respects it is probable that she had a fracture on this occasion also. For some years she was an inmate of the poorhouse, reserved for the destitute and very chronic cases. She did not at any time appear to have been destitute. From the age of 16 until the present time she had had no fractures.

Clinical Examination

The only thing of note about the patient, apart from the deformities, was the blue colour of the sclerotics, which is very striking in a coloured person. Her height was 4 ft. 10 in. reduced by the shortening of the lower limbs. All the long bones of the lower limbs were grossly deformed, particularly the left femur, which was bowed forwards and outwards, and the right tibia and fibula bowed forwards and inwards—well shown in the accompanying photographs. The anterior superior spines

fossa, and separate from the broad ligament The ovary measured about two and a half inches by three quarters of an inch, its surface was unusually smooth and glossy, but signs were present of a recently ruptured follicle The left ovary was then examined and found to be similar in situation and constitution Except for extreme length, the Fallopian tubes were normal their ostia lying adjacent to the proximal poles of the ovaries The uterus was not fully developed, but showed no obvious abnormality

The caecum and appendix were next sought for, but could not be found in the right half of the abdominal cavity The caecum was finally discovered lying in relation to the greater curvature of the stomach with a long bulbous appendix attached The large intestine consisted therefore of the caecum followed by a length of about four inches of colon—to which was attached a thin and scanty great omentum—leading direct to the splenic flexure From that point to the rectum nothing abnormal was found except that the sigmoid flexure was extremely large and reached well over to the right side The kidneys showed foetal lobulation but were not joined, no further internal abnormalities were discovered

Externally the girl was well developed for her age, and devoid of malformations

More special inquiry into the patient's menstrual history elicited the information that her periods had started three months previously and had so far been regular The abdominal pain was thought to have been particularly severe at these times and this fact would seem to indicate that the symptoms for which she was admitted to hospital were most probably associated with the malposition and abnormal development of the ovaries

IMPLANTATION OF CARCINOMA BY AN OPERATION

The following notes of a case of an unusual form of recurrence of growth, following an excision of part of the colon for carcinoma are, I think, of sufficient interest to merit publication

A man aged 36 had had, eighteen months previously, two operations for abdominal trouble In the first one, the bowel was drained through an incision in the right iliac region, and on the second occasion a growth was excised from the descending colon Since then he had been quite well until a few weeks before seeing me, when he had vague abdominal pains, occasionally feelings of abdominal distension, and once, during an attack, he vomited

On examination I found two scars a left paramedian incision, and a smaller one on the outer side of the right rectus, which had obviously had drainage through it Beneath the latter scar I detected a tumour firm to the touch, dull on percussion, and slightly tender

A right paramedian incision was made and the caecum was found adherent to the abdominal wall by several fairly dense bands These were divided and the caecum was completely freed except for the appendix, which was anchored on to a dense hard mass adherent to the under surface of the old scar I divided the appendix at the base and invaginated it in the orthodox manner I then excised the appendix and tumour in one piece together with the skin incision to which it was adherent There appeared to be no evidence of infiltration of the tumour through the parietal peritoneum I then examined the anastomosis in the descending colon This was patent and free from adhesions and there were no adhesions to any other part of the abdominal cavity, or evidences of metastases in the liver spleen, glands mesentery omentum, or pelvis The incision was then closed the patient made an uninterrupted recovery

Examination of the tumour showed a mass of what appeared at first sight to be chronic inflammatory tissue and adhesions with the appendix running right through the centre of it A stained section under the microscope showed definite adenocarcinoma Some months later he returned with evidence of recurrence in the pelvic peritoneum and glands

In view of the fact that at the time of operation I could find no other evidence of growth in the abdomen I can only conclude that at the previous operation an appendicostomy had been performed after the original growth had been handled by the operators, and that carcinoma had been implanted round the appendix at the same time If this is so, it is a reiteration of the fact that one cannot be too careful in the precautions taken when operating upon cancer or other allied new growths

DIAGNOSIS AND TREATMENT OF MALIGNANT DISEASE OF THE CHEST

At the meeting of the Medical Society of London on November 10th, with Dr R A Young in the chair, Dr Chevalier Jackson of Philadelphia opened a discussion on this subject

Dr Chevalier Jackson said that the bronchoscopist lacked the broad viewpoint of the internist and the surgeon Therefore he himself could not hope to present comprehensively such a subject as the one for discussion that evening When it came to a foreign body in the lung the bronchoscopist felt himself entitled, out of his large experience, to speak There was, however, some consolation in the fact that clinical experience was always clinical experience, and clinical facts were always of value Experience was what one got when one was looking for something else, and that was particularly true in cancer of the lung All discussion on cancer in any site began and ended with early diagnosis probably also that applied to other things besides cancer Dr Jackson proceeded to show on the lantern screen the radiographs of various cases of malignant and semi-malignant growths encountered in his bronchoscopic clinic The growths included chondroma, chondro-osteoma endothelioma carcinoma, sarcoma lymphosarcoma, lymphomyxoma, and neurofibroma He mentioned that when forty years ago, he first saw a case of cancer of the oesophagus, he thought there was a great era ahead for the treatment of such a condition The mortality was at that time 100 per cent, and it was still 100 per cent to-day He mentioned that only by way of contrast Cancers of the oesophagus were not sensitive, apparently, to x ray treatment, whereas many cancers of the lung seemed to be radiosensitive, though there were others in which the rays had no effect His experience at his bronchoscopic clinic was that there were some malignant growths in the lung which were of a very low grade of malignancy quite amenable to treatment, and sensitive to x rays Whatever might be thought of the operation of lobectomy there was this to be said—that it had never had a fair chance, because the cancer of the lung was practically never diagnosed sufficiently early Diagnosis of pulmonary cancer was usually very late, and always would be so unless every patient with pulmonary disease was examined with the bronchoscope He proceeded to discuss the valvular action of the bronchus, repeating to some extent the remarks he made in his lecture at the Royal Society of Medicine on October 14th (extensively reported in the *British Medical Journal* of October 25th p 702) He mentioned that a wheezing sound plainly heard when the examiner's ear was close to the patient's open mouth, but not heard at the chest, might be a significant sign in the diagnosis of pulmonary cancer though at the same time it might denote other conditions some of them trivial In conclusion Dr Chevalier Jackson said that he was not very enthusiastic about the implantation of radon seeds in the lung, nor, indeed, about any line of treatment of cancer Mechanically it was easy to insert radon seeds but he was not at all certain as to how much could be done in the way of curing cancer by this method It seemed to him that lobectomy and radiology had to be looked to for alleviation, until more was known about the etiology of cancer and the methods of treatment It was a platitude to say that the diagnosis of cancer should be made early, but it was not so well known that the only way of making an early diagnosis of cancer of the lung was to put in the bronchoscope It seemed to him that the greatest good would accrue from the close co-operation of the surgeon, with his broad point of view on the general problem of cancer, the internist, who could look and listen on the outside the radiologist, who could in a sense look through the patient and the bronchoscopist who could look inside the lung

Mr V F Nash said that there was an erroneous impression in this country about the work of Dr Chevalier Jackson—namely, that it was principally concerned with

which, it was ascertained, at least five came from different manufacturers Dosage was measured in milligrams per kilo of body weight With a given sample it was found that 70 mg per kilo of body weight injected intravenously into a large number of mice caused the death of 10 per cent within seven days 150 mg per kilo injected into the same number was fatal to all From these results it was possible to estimate the average lethal dose, or the amount of mercurochrome per kilo of body weight which would produce the death of 50 per cent of the animals The results with two of the preparations might be expressed as follows

Results with Sample I

Dose in Milligrams per Kilogram	Number of Mice Injected	Percentage Mortality Within Seven Days
75	10	100
45	60	71 6
30	30	30
20	10	0
Results with Sample II		
160	30	83 3
140	30	60
120	30	20

The average lethal dose of A was 37 mg per kilo, while that of H was 138 mg per kilo, in other words, A was 3 73 times as toxic as H A few years ago there had been agitation over the standardization of neosalvarsan, and, as a result, a variation of toxicity of more than 20 per cent was now considered to be serious In the case of mercurochrome the range of toxicity of samples on the market was considerably higher than this Five out of the eight samples, however had a toxicity such that the average lethal dose was not less than 105 mg per kilo, and this was suggested as a suitable minimum which should be demanded in standardization, while the sale of samples more toxic than this should be discontinued It was observed that the least toxic sample contained the amount of mercury which approximated most nearly to the theoretical, but the quantity of mercury was in no sense proportional to the toxicity, and could not be taken as an indicator The least toxic samples were not necessarily produced by the biggest firms, and it was evident that the manufacturers were not applying toxicity tests of any value It was the business of the medical profession to demand standardization

Sir William Willcox pointed out that mercurochrome was a toxic drug which was used particularly in desperate cases, and when a good result followed its use it was not easy to say whether it was *post hoc* or *propter hoc* It was difficult to judge the effect of a drug in a toxic condition, and a physician was continually impressed with the ease with which, in critical cases, a small thing might turn the scale unfavourably, and provoke, say, a fatal haemorrhage Mercurochrome was a toxic preparation, if only on account of the mercury which it contained As a toxicologist he had frequently observed the patient who, after a dose of five grains of mercuric chloride, appeared to recover, with complete subsidence of gastro-intestinal symptoms, yet on the fourth or fifth day suppression of urine inevitably set in and the patient died of uraemia Mercury, moreover, might provoke a severe type of ulcerative colitis and was a liver poison By means of experiments on animals and humans, and by bactericidal tests, the use of mercurochrome had been investigated at St Mary's Hospital, and the conclusion had been reached that it reduced the bactericidal power of the blood He thought this drug should be relegated to the time when it was known to be standardized, and when it was not only harmless to the normal person but to the patient in extremity

Dr E P Poulton had given mercurochrome intravenously to a child with a congenital heart lesion upon which had supervened an infective endocarditis He had found it to do neither harm nor good, and Dr Hamill endorsed that view of the effects of the drug Dr Ivor Bennett had used it in a case of septicaemia without result Some weeks after it was stopped the man had developed a fixation abscess spontaneously

Mr K W Heritage had found mercurochrome to be valuable when given intravenously in cases of appendix abscess where the patient ran a swinging temperature following operation The temperature usually settled completely after the third or fourth injection As a wash out for the renal pelvis in cases of pyelitis it was disappointing, but in intractable cystitis with frequency of micturition and pyuria he had had good results from its use as a wash, especially among women

In reply to Dr H S Stannus, who asked whether the virtue of the drug lay in the mercury, or whether any special blessing was to be attached to the fluorescein, Dr Burn said that he believed mercurochrome was supposed to have specific bactericidal properties as an individual compound He knew of no form in which mercury had been omitted

Dr Stannus also raised the point of investigating the renal function before the drug was given since mercury was supposed to be the important agent Recent investigation of the importance of some of the arsenical preparations in trypanosomiasis had revealed the fact that results were due not to the arsenic, but to a member of the benzene group

Dr L C Rivett had employed mercurochrome intravenously in puerperal sepsis with disappointing results When the infecting organism was a streptococcus, particularly when it was haemolytic, he had observed no reaction from the use of the drug There was more hope if the infection was due to *Bacillus coli* As a local application mercurochrome was undoubtedly of benefit, and he had known some cases of chronic cervicitis to respond marvellously when treated with the drug in the form of a douche or a paint He had not used it for acute gonococcal cervicitis or for pyosalpinx

Dr G Graham asked for details of the bactericidal powers of mercurochrome, and wished to know whether addition to blood rendered it more potent Dr Burn, replying, referred him to the original paper by Young, White, and Swartz He reminded his hearers that the difference of toxicity of the various samples was not an argument against the ideal use of mercurochrome It could be remedied by the manufacturers and it was the business of the medical profession to demand that toxicity should be uniform

Dr Graham suggested that it was the business of the body responsible for the *Pharmacopoeia* to demand standardization Dr Hamill replied that, while it was one of the functions of the members of that body to define drugs in common use, they were at liberty to omit any drug not extensively employed if they saw fit It then became the responsibility of the medical profession to demand standardization by the manufacturers

VASCULAR TUMOURS OF THE BRAIN AND SPINAL CORD

At a joint meeting, on November 13th, of the Sections of Neurology and Ophthalmology of the Royal Society of Medicine, with Dr Leslie Paton in the chair, a discussion on vascular tumours of the brain and spinal cord was opened by Dr A Lindau of Sweden

Dr Lindau said that the recent classification of these tumours into angiomatous malformations and haemangioblastomas, by Cushing and Bailey, signified a great advance as the two types differed from each other in site, histological picture, and clinical signs, and required different treatment Those in the first group showed traces of compressed glious nervous tissue between the vascular loops, they were met with in both the brain and the spinal cord, and might occur as part of a systemic disorder with coexistent trigeminal naevi, unilateral glaucoma, and homolateral pial angioma showing a tendency to calcification on x-ray examination In some cases the angioma extended to the ventricle, and death might be by haemorrhage The syndrome often occurred in young children, and four Scandinavian cases had been reported, but a

the level of the seventh and eighth cervical segments which showed reticulum, no capsule, and tongues of glia extending into the tumour The cavernous haemangiomata found above the tentorium consisted of closely packed blood spaces, and appeared to have no connexion with the meninges, they formed no cysts and were not encapsulated, the blood spaces were thin-walled and there was often a striking production of collagen reticulum Frequently the blood spaces were separated by strands of glia, and in one case there was a development of bone trabeculae in the collagen In two cases she had found associated abdominal lesions taking the form of kidney malformations and islets of suprarenal tissue, with cyst formation, in the kidney cortex These tumours, then, showed non-encapsulated capillary and cavernous spaces, separated by glia and by collagen reticulum, but with no evidence of endothelial proliferation, glia might be found in the true haemangioblastomata, and if reticulum was to be the criterion of recognition, there was a danger of confusion There was no doubt that these tumours formed a group distinct from the subtentorial growths and from the cirsoid angiomata, but their connexion with Lindau's syndrome must at present remain open

Mr L B RAWLING described the case of a boy who had an angioma of the frontal lobe, at operation no vessels were ligatured, but five years later he had appeared with a haematoma over the right side of his face This had subsided, and he was now well He was able to quote the histories of other cases of the same kind

Dr PARKES WEBER asked what was the type of angiomatous conditions of the skin when they were found associated with the cerebellar haemangio endotheliomata of Lindau's disease He would expect them to be either haemangio-endotheliomata or haemangio xanthomata, and would like to know whether this was indeed the case He would also like to know the nature of the cystic condition of the kidney and pancreas when it was found in association with this syndrome

Dr H COHEN showed some of the radiographic changes in the skull which might be found in cases of angiomata and Dr W G BARNARD described a case of capillary angioma found above the tentorium, which on section was similar to the other cases described

In replying, Dr LINDAU agreed that a history of trauma was often recorded He believed the haemangio-blastomata to be congenital, and thought the apparently fresh development of previously unsuspected growths in the retina was due to their small size in the early stages He was interested in Miss Russell's cases, especially those where cavernous angiomata of the brain had been found associated with cysts in the kidney, but he did not think they formed a link between angiomatous malformations and capillary haemangiomata A cystic pancreas was not found among her cases, and he thought it was still wise to keep the groups distinct Naevi in the skin associated with capillary haemangiomatosis were rare, and no histological examination had been made of them in the two cases recorded The cysts found in the kidney were not related to the congenital polycystic condition

THE STUDY OF HYSTERIA

IN the Section of Psychiatry of the Royal Society of Medicine, on November 13th, Dr S A KINNIER WILSON delivered an address from the chair entitled "An approach to a study of hysteria"

Dr Kinnier Wilson began by remarking that possibly the outstanding feature of hysteria as revealed by the records of former generations and the knowledge of the present was the changes which its clinical syndromes had undergone The mediaeval ecstatic, simulating in hands and feet the nail-prints of her Redeemer, was long since forgotten, as was her eighteenth century sister, melodramatically counterfeiting the emotional transports of a popular actress The speaker quoted an account of a visit by Mrs Siddons to Edinburgh, when there were repeated scenes of fainting and hysteria among the girls and women in her audiences The chronicler told how a popular surgeon was most reluctantly getting out of the pit to attend some fashionable female, when a friend said to him in passing (alluding to Mrs Siddons) "This is glorious acting, Sandy," to which he answered, looking round at the fainting and screaming ladies in the boxes, "Yes, and a damned deal o't too" "To day," said Dr Wilson, "we seek the clue to the ailment in the unseen psyche, and she [the poor hysteric] is somewhat at a loss accordingly, her elaborated somatic manifestations are rather at a discount A cold scientific environment besets her, instead of a world of emotional extravagance and unlimited credulity So a defence-hysteria is now well *a la mode*, no less egocentric if more utilitarian, with an eye on the main chance, the hysteric turns to the possibility of compensation for trauma, or seeks to escape from unpleasant reality by a flight into neurosis—at least, so we are assured The times have changed, and we, both physicians and hysterics, have changed with them" Yet when all was said, it remained true that if hysterical fashions varied, their kaleidoscopic patterns were composed of unaltering instinctive and impulsive reactions Thus its clinical characters could be recognized on the Greek vase depicting the ecstasies of the frenzied maenad, in the records of some New Testament miracles, in mediaeval paintings of demoniac exorcism, in modern accounts of camp meetings, spiritualistic seances, and religious revivals, of disease mimicry in schoolgirls, and shell-shock amid twentieth century warfare Beneath surface diversities the essence of the phenomena involved had not been modified Further, where old beliefs lingered in the public mind, where superstition and mysticism were rife, there still was to be found the favourable milieu for hysterical exhibitions of antiquated form even in this epoch of scientific enlightenment Human culture might make progress, but a Messina earthquake or a world war would lay bare hidden reactions Old as were leprosy, rabies, and malaria, epilepsy and hysteria were older still, perhaps as old as human nature itself

Proceeding to discuss the motor system in hysteria, Dr Wilson referred to the occurrence in hysterical palsies of the phenomenon known as "defective inhibition of the antagonists" For example, when a patient was asked to extend the elbow, the first muscle observed to contract was the supinator longus, one of the antagonists to the movement of extension Thus was the most common motor sign of the affection Another no less interesting motor sign consisted in the shunting of the desired innervation to other groups of muscles not confined to the actual antagonists For example, on the patient being requested to grasp the examiner's fingers tightly, she would give the impression of putting forth great effort, but the grasp would remain feeble, though shoulder muscles and others remote from the long flexors were found in strong contraction Both these signs indicated impairment of cortical function, coupled with defective inhibition With regard to positive movements, hysterical tremors presented no separate or contrasting features when set alongside those of the so-called "organic" type In hysterical as in organic states, tremor was an escape phenomenon of an infra cortical level So far as the multiplex syndromes under the category of the hysterical fit were concerned, their range from fugues at the one extreme to immobility and lifelessness at the other covered so wide a somatic field as perhaps to render attempts at synthesis precarious Reduced, however, to their lowest terms, one and all were indicative of release of function from conscious control Differences between hysterical and epileptic fits were matters of degree, and not of kind, and if more profound in the average major epileptic seizure, this might be more serviceable in clinical diagnosis, but not in nosological differentiation Turning to the sensory system, Dr Wilson said that, before assuming that hysteria was a "disease of the mind"—a disorder on the plane of mental images—it was well to recall that the physiological arrangement of the mechanisms underlying conduction of sensory impulses varied at successive neural stages Peripheral loss of sensibility could be distinguished from spinal loss, spinal from thalamic, and thalamic from cortical He instanced various facts which made it rash, in his opinion, to presume a psychogenic basis for sensory disorders because of peculiarities in their segmental type when there was

cases These meetings should be part of the routine of hospital work, and should be attended by students He feared that the teaching of full-time medical professors was very likely to be divorced from the necessities of actual practice, full-time research workers in the hospital (provided funds were available) would be much more likely to advance knowledge than part-time workers, but they often became too interested in purely academic questions As far as possible the problems of general practice were those that they should endeavour to solve One variety of research which could be undertaken as well in Dublin as elsewhere was the following up of end-results, the type of work which the late Sir James Mackenzie had shown to be so important The ultimate results following surgical proceedings had been very imperfectly observed in the past and there was a great field there for the collection of facts The after-history of patients in whom biochemical tests had been performed was also very scanty, many more facts must be collected before the validity of biochemical actions could be accepted

Dr W BOXWELL remarked that biochemistry was no new or isolated part of medicine, but had been an absolute necessity from the beginning Harvey, the great physician was his own anatomist, physiologist, surgeon, and apothecary in his day there was no such thing as organized pathology In Ireland any effort at organized research was hampered at the beginning by lack of funds, and clinical research at present was in a rather chaotic state The more departments there were in a hospital, and the better run they were, the more chance there was of making such research work as was possible available for the patients who were under treatment All the special subjects were flourishing independently, but the speaker suggested that it might be possible for their teaching to be carried out in one special institution, there being a liaison officer between that institution and the hospitals The students could be attached to the hospitals as well for medical and surgical work in them, and undertake also research work in the institution

Professor J M O'CONNOR said that the foundation of medicine was physiology, which subject should be brought more into the life of medical students Doctors were concerned with the living patient and not with the disease that the patient was suffering from, and the methods applied to living patients must of necessity be applied to sick people Biochemistry was held at the present time in exaggerated regard, and was really only a part of physiology The fault in medicine in many countries was the attitude of leaving physiology behind It was not easy to see how students should be trained into the methods of research, but he suggested that the junior appointments in the hospitals should only be made on the results of scientific progress, in conferring higher positions the fact whether the candidate had done any research work or not should be taken into consideration It was easy to carry on very good research work in very small laboratories, and he thought that young men should be compelled to do two years' clinical laboratory work before they were allowed to do hospital work

Dr R J ROWLETTE said that most of those who were engaged in clinical work realized that the basis of that work was almost entirely physiology Workers in laboratories chose the conditions for their experimenting, and had not the same complexities to face as had workers in hospital wards, but it was essential that those who worked in hospital wards should be well trained in laboratory experimental work, so that the methods carried out in the wards would bear the scrutiny of the laboratory In times past there had been a danger of medical study becoming too purely clinical, and something more was still required in the way of experimental work The speaker referred to the student's need of a book on elementary logic and statistics, and mentioned mistakes sometimes made in the classification of results Mr W DOOLIN agreed that every medical student ought to have an elementary training in logic, but he thought the practical training of students in the hospitals of this country was much more useful than that in France or in Germany, from the point of view of fitting them to become practitioners

Reviews.

"CANCER OF THE LARYNX"

A BOOK on a subject that is exercising the minds of the profession supplies a definite need, and when its writers are foremost among those who have advanced our knowledge of it, a work such as *Cancer of the Larynx*[1] is sure to receive a generous welcome Its authors, Sir STCLAIR THOMSON and Mr LIONEL COLLEDGE, have made the subject peculiarly their own by many years of close study, and now present the results based on personal work and experience, with admirable fullness and clearness The former has seen intrinsic cancer of the larynx pass from being a dire disease to become one of the most amenable from a surgical standpoint, and has himself contributed in no small degree to this striking change The latter, from his work on the more advanced stages of the affection, has earned the right to speak with authority Despite its dual authorship—perhaps because of it, for each forms a complement to the other—the book has been put together with a thoroughness and independence of judgement that seldom fails to satisfy

We owe mainly to Butlin and Semon the pioneer work which has revolutionized our views of malignant disease of the larynx and has been the basis of subsequent progress It is realized that intrinsic cancer of the larynx is more common than extrinsic, and that the former is most frequent at the cord site and never appears on the posterior commissure or interarytenoid space The authors hold that the subglottic variety is not so rare, but most difficult to recognize and often overlooked They have no belief in a pre-cancerous condition The great advance was recognition that cancer arising in the interior of the larynx is usually slow in growth and relatively benign, only invading glands in an advanced stage On the other hand the extrinsic form is a dire disease Early diagnosis is the pivot upon which much—very much—depends in cancer of the larynx It offers every promise, almost certainty, of a lasting cure in the extrinsic form it is the chief hope With this few will disagree A persistent hoarseness, especially in middle life, is a warning sign, and this cannot be too often repeated All this is brought out with great lucidity and force

The principles of treatment are fully laid down In removal, laryngo-fissure is the route preferred From being an operation with a high mortality, improvement in early diagnosis and technique has made it safe It is the only line that affords satisfactory approach for adequate removal and requires excision of one ala of the thyroid cartilage It has in fact become a partial laryngectomy, giving freer access to the field and better healing This striking advance we owe in great measure to the work of Sir StClair Thomson himself In laryngectomy the great advance is seen in restricting it to intrinsic cases which are too far gone for laryngo-fissure The local conditions which indicate it are well brought out and the importance of the general state of the patient emphasized, as might be expected from the wide outlook of the authors Laryngectomy has become a great achievement, with a surgical mortality which has fallen from 50 per cent some few years ago to 3 per cent, and to this a scrupulous attention to preliminary care and after-treatment has contributed much Opinion is still fluid in regard to operations for extrinsic cancer involving the pharynx Gluck and Soerensen prefer a total laryngectomy, MacKenty of New York holds all surgical procedures hopeless, while the British school, taking a middle line in keeping with its geographical position, gets a fair proportion of lasting results from pharyngotomy in suitable cases

In this work the authors have made it their aim to afford a complete view of the present position of this important question They have explored all aspects of it, and their verdict will carry great weight Not only does the book give a wide conspectus of the whole field, but its judgements on the more important problems are likely

A MEDICAL MISSIONARY

The book entitled *Dr D Duncan Main of Hangchow*[10] is a record of the life and work of a leading stalwart in the medical missionary world Scotland has contributed a remarkable proportion of men whose names have become famous, each of them endowed with native ability, an untiring persistence to accomplish great things, and a winning personality Such men were Livingstone, Stewart of Lovedale, Laws of Livingstonia, to mention but a few, and to this roll of honour must be added the name of Duncan Main of Hangchow In 1881, at the age of 25, Dr Main, accompanied by his young wife, sailed for China, and was sent on arrival in Shanghai, by the Mid-China Mission, to Hangchow, the capital of Chekiang Province The first chapter contains a description of Hangchow, which for past ages has been so renowned for its beauty that it is known to the Chinese as "Heaven below", and in the second chapter the religions of China are described The rest of the book deals with the life-story of its subject

Dr Main first began his work by opening a dispensary He worked, begged and prayed for a larger hospital," and two years later was able to lay the foundation stone of it Its Chinese title was the "Hospital of Universal Benevolence" He was its architect, general overseer, lecturer physician, and surgeon, and from it sprang in course of time the various departments which made the name of Main of Hangchow so celebrated among Chinese and foreigners alike As the story unfolds it tells of how an opium refuge an isolation hospital, a leper hospital and a maternity hospital, a home of rest for pastors and workers all came to be opened, and we are given instances of the work amongst sick blind, deaf and lame people—in fact, all the "under dogs" who required a helping hand Throughout it all this devoted couple kept the spiritual part of their duties ever in the *forefront* There are many little delightful pen-portraits of the Chinese men and women among whom they lived and laboured For those who may feel the need of encouragement (and life is only worth living for the courage we bring into it) there is a feast in reading about all that 'Dr Apricot" accomplished We gather that from the time of his arrival at Hangchow, when he had found one small house with sixteen beds for opium addicts till the time of his departure forty-six years later, Dr Main had, by his own initiative, established twenty-one departments and hospitals—surely a remarkable achievement

The volume is well illustrated, and has been compressed to the handy size of 244 pages It will make the reader wish to have a further insight into the life and times of this cheery doctor and his able wife What though the Chinese Republic is passing through troublous times and much of the work has been ruined by misguided political malcontents? There is here the record of nearly fifty years' wonderful usefulness, which has deeply imprinted itself in the hearts of too many Chinese to be permanently effaced

NOTES ON BOOKS

Dr R A Houstoun's well known *Treatise on Light*,[11] first published in 1915, has now reached its sixth edition This book is rather more advanced than the ordinary medical student requires but to those proceeding further with the study of physical optics it can be strongly recommended The latest edition shows evidence of thorough revision, and includes more than twenty new diagrams and a new index

There is appearing under the able editorship of Lieut-Colonel J Stevenson, I.M.S (ret.), a series of monographs on *The Fauna of British India, including Ceylon and Burma*[12] and a number of these are devoted to parasites The Cestoda, for example, are described and catalogued by Dr T Southwell of the Liverpool School of Tropical Medicine, and the first volume on this group has now been published This volume contains a general introduction to the Cestoda of some forty pages and the first part of the systematic account The introduction contains a general account of the tapeworms, their classification, morphology, diagnoses, and technique, and it should be invaluable to the student of helminthology The major part of the book, however, is given over to a systematic description of the species found in India, and includes the Cestodaria, and five of the six superfamilies of true cestodes recognized by the author, the sixth (the Taenioidea) being left for the second volume Most of the species dealt with are of direct interest to the zoologist rather than to the medical scientist, apart from *Dibothriocephalus* (which the author retains instead of *Diphyllobothrium*) none of the genera occur in man But in parasitology the comparative method has been one of the most useful in understanding the forms which infect human beings, and for that reason if for no other, the volume is a welcome addition to the library shelves of the human helminthologist as well as to the general zoologist

Mr W McAdam Eccles consulting surgeon to St Bartholomew's Hospital delivered a series of addresses to the Bibbical Forum at St Marylebone Presbyterian Church and the substance of these has now been published in a small book entitled *Old Fundamentals in Modern Light and Continued Natural Law in the Spiritual World*[13] Here will be found a statement of the author's views on religion and modern science set out clearly and succinctly, in order that some of the difficulties felt by honest inquirers in the street or classroom may be met.

A bibliography of the papers read before the first six international Congresses of the History of Medicine has just been published by Dr Marcel Fosseyeux general secretary of the Société Française d'Histoire de la Médecine

PREPARATIONS AND APPLIANCES

A Modified Kelly Proctoscope

Mr W B Gabriel M.S F.R.C.S (London W 1) writes Messrs Allen and Hanburys Ltd have made at my suggestion a modification of the well-known Kelly proctoscope

The tubular part of the instrument is a quarter of an inch longer than usual allowing now a working length of 2½ inches, this length is often required for giving high submucous injections in the treatment of haemorrhoids The handle is broad and flat, 5 inches in length it is set at an angle of 115 degrees, and in practice renders the instrument easy to manipulate and control The finish is in chromium plating

Quinisan

Quinisan (Messrs Howards and Sons) is a proprietary name for the compound quinine bisalicylosalicylate This compound separates into quinine and salicylo-salicylic acid in dilute acids, but the salicylo-salicylic acid is not hydrolysed until the drug reaches the small intestine Thus the gastric irritation produced by many salicylic compounds is avoided The drug is a combination of two powerful antipyretics, and it is recommended for the treatment of influenza and tonsilitis The makers quote very favourable clinical reports The compound is supplied in 4 grain tablets, and the dose recommended is one tablet two-hourly

considered by Masson it may be said briefly that he regards them as of the same nature as the naevus cells of the corium. Professor Ewing's comment on these investigations is that there is no longer any room for debate about the nervous origin of the naevus cell, which is now shown to be a derivative of specialized cells in the sensory nerve endings. At the same time he makes the important reservation that these observations do not dispose of the possible participation of epithelium in some manifestations of melanomata. It must, indeed, be within the experience of all pathologists that in some cases of melanotic sarcoma a down-growth of epithelial cells seems hardly to admit of doubt.

REST, WORK, PLAY

The cautionary remarks on the therapeutic value of rest, work, and play made by Sir Farquhar Buzzard in an address at the Winnipeg Annual Meeting, and printed in this issue of the *Journal*, are very opportune. It is time that we of the medical profession revised in some respects the stereotyped beliefs and practices with regard to the use of rest in the treatment of diseases. Such books as Hilton's classical *Rest and Pain* did admirable service in explaining the vital importance of rest for injured parts, although even in the treatment of bony fractures rest is now rather mingled with movement than was formerly the case. But doctors in general were so much impressed with the efficacy of rest in partial injuries of the organism, such as fractures, and in acute physical disease, that by an easy but false analogy rest came to rank almost as a therapeutic religion. Whenever there was illness, rest for a time was considered essential. How many lives have been injured, how many careers frustrated, by the prescription of rest when no rest was necessary! We have encountered a patient who, having been prescribed rest in bed thirty years before, had remained there ever since. This, of course, is a grotesque example, recalling the old woman in *Punch* who, when asked by the vicar why she was confined to bed, explained that the doctor had called three years ago and ordered her to rest in bed till his next visit—and he had not returned. But there have been many real tragedies of the rest fetish. A schoolboy presenting some functional disorder of the heart's action is told that he must rest; a period of six months or even a year is ordered. It is not so much the loss of time, which does not matter so greatly in the young, it is the very real psychological trauma produced by the suggestion of invalidism that does the harm.

In no branch of medicine has rest to be prescribed with greater care than in the functional nervous conditions to which Sir Farquhar Buzzard devoted the second part of his address. There was a time when rest in bed was the stock remedy; people forgot that resting the body was not the same as resting the *mind*, they did not even perceive, what is now common knowledge, that most such conditions depend upon a restless mind and not upon an overworked or under-engined nervous system. Too much play was made with the term "nervous exhaustion." Weir Mitchell and other distinguished exponents of the method did not realize that their cures were obtained usually in spite of, rather than because of, their method. Now the emphasis has changed, and in the treatment of psychogenic disorders generally, as well as of the severer psychoses in mental hospitals, occupational therapy, which is the reverse of a rest therapy, is coming into its own. In this country, so far as mental hospitals are concerned, it has been most extensively developed by Henderson in Glasgow, with marked benefit in all wards, not excluding noisy ones, and in Germany the "active work therapy" of Simon has produced results that have not only surprised but convinced visitors to his hospital. It is not that rest does not have its place in therapeutics, it has a very important one in the treatment of acute mental or functional nervous conditions, but it has to be prescribed with all the care that would be given to a potent drug. There are those who, having been told to rest, conclude they must be easily tired and continue to be so for the remainder of their lives.

Fortunately the importance of work is receiving greater *recognition*, not only in the treatment of psychogenic conditions, but in the rehabilitation of those who are suffering or have suffered from physical disease. No one can fail to be struck by the enormous idleness of the average hospital bed patient under the usual regime. We look forward to an early time when occupation will be a therapeutic bulwark not only in mental, but in general hospitals. Something of this sort has already been recognized in America; it is now being introduced into general hospitals here—for example, the recent enterprise in the Royal Free Hospital. It encourages, reassures, and interests those genuinely anxious to get well, and it rapidly picks out the malingerer. Work is the great solace. Nothing in the world gives more permanent satisfaction than work well done. Should we not seek, then, to let our patients have it as far as their condition will allow? While rest may be good for parts of the body, and in acute illness for the whole organism when taken excessively by the person as a whole it is demoralizing, and doubly so at almost any stage of their illness for the vast majority of neurotic patients to whom Sir Farquhar Buzzard refers. The prescription of the appropriate type of work for a given patient becomes an art in itself. Already a literature on this subject has sprung up, and there is a journal in America devoted to occupational therapy. Whether such thoroughgoing specialization is desirable is open to argument, but there can be no doubt of the need for providing some special training in the field. There is in this country a great scarcity of persons qualified both by an occupational training and by temperament for this work, yet the demand for them is bound to increase, because of their immediate therapeutic utility and because of their economic value in the long run. It has been pointed out that insurance companies may some day feel it worth while to subsidize the employment of occupational teachers in hospitals.

The correlate of work is play, and here Sir Farquhar Buzzard has some wise words to say on such advice as the familiar "Take up golf." This can be devastating counsel, if given to the *wrong* person, or at the wrong time, and it raises problems of physiological mechanics, as well as of psychology. Thus it may be quite correct to prescribe golf to one patient with a Parkinsonian syndrome and not to another, the advice depending on the presence or absence of the paradoxical motility of Souques. But the larger issue is that some people make their play too much like work—for example, the strenuous business man who drives his car sixty miles into the country at the week-end, plays thirty-six or even more holes on Sunday, and comes back to duty far more tired than when he left it. These and many other points are involved in the apparently simple prescriptions of rest and recreation.

suffered the indignity of being taken to school in an ambulance It would be a pity if discussion of such topics as Lord Riddell mentioned were to be too much encouraged among popular audiences The best kind of health education deals, not so much with profound scientific controversies, on which at present there can be nothing approaching unanimity, even among the experts, but with simpler but not less vital issues Several speakers deplored the difficulty they found in persuading editors to accept health articles for publication On this point Lord Riddell adjured members of the conference to get their teaching into the press rather by making challenging statements of crude fact than by trying to insinuate the lessons of health in syrupy articles Dr John Hall, organizer of the Merseyside Boroughs Education Committee, read a remarkable paper on the "Technique of popular health talks" It was perhaps a pity that he compressed into this enough matter for the forty-two separate lectures which he is in the habit of giving to children and others The conference was a little perplexed Queer geometrical arcs, and even stranger combinations of letters, formed themselves under Dr Hall's legerdemain into thrilling messages and a kind of health metaphysics, which showed that the speaker was a man of unusual mind At the afternoon session Professor H R Kenwood described generally the means and methods of the central council Mr G H Barker, a member of the executive council of the National Union of Teachers spoke on health teaching in the schools In his condemnation of many of the existing school buildings many members thought Mr Barker went too far, but he explained that his speech was intended to challenge complacency, and certainly he succeeded in arousing numerous apologists for present-day educational arrangements, and in eliciting some reactionary views The conference listened with great attention to Professor V Adam, the general secretary of the German Central Bureau for Health Propaganda As might be expected, this is a very complete organization Teaching is given by the school masters, and health weeks are organized generally throughout Germany One of the most interesting papers was that of Miss Norah March, secretary to the Health and Cleanliness Council, who has given much thought to the psychology of health publicity which is akin to advertising She advised the preparation of simple health articles, cunningly disguised under attractive non-scientific titles, in this way she had no difficulty in securing their acceptance The members were interested also in the question of the colour in which health posters should be printed, apparently red and magenta are antipathetic shades which arouse hostile instincts and had better be avoided Mr T Crewe, publicity organizer of the Central Council, also read a paper on the production and application of propaganda Between the sessions some excellent demonstrations were given of newer health films, including one with talking characters

THE CHURCH AND MEDICINE

One of the resolutions of the recent Lambeth Conference called for co-operation between the clergy and the members of the medical profession This was put forward as an urgent need, because the spiritual and the physical treatment of the sick were complementary and equally necessary for true well-being It was not quite clear what measures were recommended for bringing this co operation about, nor in what directions it could usefully take shape beyond the general friendliness and respect as between the parson and the doctor which exists already It has remained for the Convocation of the Province of York to carry the matter a step further In the Lower House last week Bishop Frodsham, vicar of Halifax, moved to ask the President (Dr Temple, Archbishop of York) to convene conferences in the spirit of the Lambeth resolution His idea was that conferences should be held in Leeds, Newcastle upon-Tyne, Liverpool, Manchester, and Sheffield, the five university cities in the northern province which have medical schools, with a view to an approach to a closer co operation with medical men on the subject of health and spirit There were signs, said Bishop Frodsham, that the connexion between the spirit and the body in the realm of healing was being forgotten He appeared to feel that the true relation was being obscured by forces from two opposite sides on the one hand a materialistic philosophy, and on the other such a principle as Christian Science, which maintained that health and disease were entirely of the mind He thought that conferences between clergy and doctors might result in a better mutual understanding of the work of both His resolution was seconded by Canon Brook, vicar of Doncaster, and carried The Archbishop of York, to whom the resolution was committed for further action, has on many occasions spoken on this subject One of his most notable deliverances was the sermon which he preached at Manchester in connexion with the Annual Meeting of the British Medical Association in 1929[1] He then stated that physical healing and the healing of the soul, although best carried out by separate hands, were not really different ministries They were one, he said, in the purpose of God for His world It is not a vague merging of these two ministries that will make for human good but rather a clearer apprehension of the possibilities and territory of each

PUBLIC HEALTH CONGRESS

More than a thousand delegates, representing local authorities, voluntary societies, and hospitals, have been attending this week a Public Health Congress and Exhibition, held under semi official auspices at the Royal Agricultural Hall, London The Minister of Health, who performed the opening ceremony, remarked on the vast organization which lay behind the fundamental health services of the country, and prophesied for the congress that it would be a powerful influence in increasing the interest in the various aspects of the health problem At the first session the address was delivered by Sir Arthur Newsholme, on "Medicine and the State" He criticized severely certain aspects of the insurance medical service, and his criticisms were immediately answered by Dr Brackenbury, Chairman of Council of the British Medical Association There was a lively, though good-humoured, interchange of contrasting opinion, but we have not space in this issue for an extended report In addition to the sessions of the congress proper, a number of public health and sanitary associations held meetings at the hall The first of these was the British Hospitals Association, which called a discussion on hospital contributory schemes Sir Harold Pink, the chairman of the association council, urged the need for examining the various schemes which were in being in various parts of the country, and bringing them into line One point of policy which it was very necessary to determine was whether public assistance hospitals should be included Some schemes, he said, did not provide for anything of the kind, supporting only the voluntary hospitals in their districts, while others, like the scheme on Merseyside, included appropriations to municipal hospitals also Sir Harold Pink insisted that contributory schemes ought to confine their appeals strictly to their own areas Two or three schemes in London had "poached" in the provinces, thereby causing some difficulty to the British Hospitals Association In the general discussion the delegates from various hospital centres related their experiences, and Sir Robert Bolam expressed the point of view of the British Medical Association A questionary has been prepared, and is to be sent by the British Hospitals Association to

INDICATIONS FOR TREATMENT IN PULMONARY TUBERCULOSIS

DR BURRELL'S MITCHELL LECTURE

THE Mitchell Lecture was delivered before the Royal College of Physicians of London by Dr L S T Burrell on November 13th, his subject being "Indications for treatment in pulmonary tuberculosis" The following is an abstract of the lecture

It is usually a simple matter to decide whether a patient has been infected with tuberculosis, but it is often extremely difficult to decide whether or not the lesion is active The problem commonly comes before the physician in one of two ways either he is asked whether such symptoms as lassitude, wasting, cough in a patient previously healthy are due to active tuberculosis, or whether in a patient who admittedly has had pulmonary tuberculosis the disease is active or arrested

There is a wide difference of opinion on the subjects of infectivity and immunity Tuberculin has brought out the fact that a large proportion of human beings are infected with tuberculosis, yet only a few develop clinical tuberculosis To submit a person to a long course of unnecessary treatment may do untold harm by leading him to study *his health too much* and to develop fads, it may be much worse for a child if taken away from school and companions of like age On the other hand, active tuberculosis is amenable to treatment in the early stages, and if neglected quickly gets out of control Doubtful cases should be watched at frequent intervals, but only after the fullest consideration should a patient be diagnosed as tuberculous and sent away for a long course of treatment It must be remembered that if tuberculosis is lurking in the body a prolonged holiday will not necessarily prevent the development of the clinical disease, and the patient would be better following his usual occupation under medical supervision

If we believe that a small infection or series of infections protect the individual effectively, then the correct procedure is to treat those who fail to react to tuberculin by exposure to infection or by inoculation The opposite view is *that prevention should* aim at the abolition or dilution of all sources of infection According to the first view it is those who fail to react to tuberculin who are in danger, according to the second view the reactors are not effectively protected, and are in danger from activation of their own lesions and from reinfection If sufficient living tubercle bacilli are injected into an animal which has not previously been infected there is no immediate reaction, but later it dies of generalized tuberculosis If tubercle bacilli are injected into an animal which has previously been affected the immediate reaction may be fatal, but if it survives recovery may take place without any actual disease developing, or if the disease occurs it progresses slowly and is associated with attempts at healing

There is definite evidence, then, that resistance develops from infection, in the sense that the addict is resistant to morphine, but this is different from resistance such as is *produced by vaccination against* small-pox In the usual type of tuberculosis seen in infancy the child resists the disease and fixes it in the glands Children are particularly free from pulmonary tuberculosis until they reach the age of puberty, but in girls of 16 to 20 years of age the mortality from pulmonary tuberculosis is greater than that from tuberculosis from all causes in the infant To explain this by assuming that resistance to tuberculosis is lowered by the strain of puberty seems to be unconvincing Nor is there any falling off in the number of reactors to tuberculin as puberty and the great increase in the incidence of tuberculosis occur No recognized method of protection against tuberculosis has been evolved either by tuberculin or emulsion of living bacilli The reported success of experiments with B C G still awaits confirmation

The body develops defensive powers against any poison gradually introduced One would expect the chronic consumptive to have considerable resistance, and, in fact, he has If he has no resistance he dies rapidly before he has had time to become a chronic consumptive True immunity, as it occurs after small-pox, is a different thing from the resistance which develops from habit in such cases as alcohol or tuberculosis There is no real protection, and death from tuberculosis occurs in the majority of cases

For these reasons failure to react to tuberculin is not an indication for treatment Any attempt to protect by tuberculin or tubercle bacilli seems to be wrong The policy that appeals to us most is to prevent infection or to dilute it as far as possible Where this has been done by sanitation, cleanliness, and correction of overcrowding, tuberculosis has decreased There is no evidence that any success has followed attempts to diminish the incidence of the disease by producing immunity, and in some cases, where attenuated tubercle bacilli have been injected, fatal tuberculosis supervened

Indications for Treatment in Suspected Early Cases

If the patient reacts to tuberculin he has been infected, *and the problem* is then to decide whether the symptoms are the result of a tuberculous lesion or due to some other cause The absence of cough may be taken as evidence against the diagnosis of pulmonary tuberculosis Paroxysmal morning cough accompanied by vomiting is not uncommon in the later stages of the disease, but is more frequent in alcoholics with bronchitis Cough developing suddenly and lasting more than a month is suggestive, and of 611 patients admitted to Brompton Hospital with pulmonary tuberculosis it was the first symptom in 44 8 per cent Sputum is often absent in the early stages, and a negative sputum test taken early is of little value, but when it has become purulent failure to find tubercle bacilli *is strong evidence* against the disease being active tuberculosis In only 9 out of 188 cases reported by Kingston Fowler from Midhurst Sanatorium were tubercle bacilli not found at the first or second examination In early active disease *there is usually some rise* of temperature in the evening It is increased by exercise, so that when investigating a case the temperature should be taken immediately after exercise, and subsequently at intervals of fifteen minutes, in order to note the time it takes to fall A slight evening rise of temperature alone is not enough for a positive diagnosis Night sweats are common in the early stages, but usually disappear when the patient is put to bed True night sweats are suggestive of the acute stage, and in chronic cases indicate an acute exacerbation Loss of energy is present in the great majority of cases, and is almost invariably associated with some localizing symptom, such as cough In the early stages loss of weight is often slight, loss of voice is an occasional early symptom, and if tuberculous laryngitis is found it should be assumed that the lungs are affected Dyspnœa is not common in the early stages, but digestive troubles are occasionally the *first symptoms noticed* by the patient If no other cause can be found for haemoptysis it should always be taken to indicate tuberculosis of the lungs It is common in chronic fibroid cases, and often no treatment is required except during the actual haemorrhage In the majority of cases, especially in those previously supposed to be healthy, haemoptysis indicates active disease Idiopathic pleurisy is almost invariably *tuberculous*, if it occurs in the apparently healthy as a result of a chill or sitting in a draught it should be regarded as tuberculous in origin, and in some 40 per cent of cases goes on to a definite form of clinical disease

If no physical signs are found it is no evidence whatever that the patient is free from tuberculosis, on the other hand, physical signs are important, not only *because* they are occasionally the first indication of disease, but because they frequently enable one to judge the spread of it The only physical sign which is really important is the presence of moist sounds over the upper part of the lung, and if these sounds are constant and increase with cough *they* are almost pathognomonic Other signs, such as slight flattening at one apex, impairment of percussion *note, and* altered vocal fremitus, may be misleading "Examine your patient carefully, but put not your faith in physical signs" The correct interpretation of x-ray findings is a matter of difficulty Fine mottling of the lung, especially

owed a great deal to latter-day co-operation between the society and the British Medical Association, and it was the best possible augury that Dr Willoughby should have been chosen for the presidency of the Association

SIR EUSTACE HILL recounted some of his early experiences, first as medical officer of health for South Shields, and later for County Durham Durham and Glamorgan were, he believed, the only counties where Labour was in power on the councils, and from the point of view of the medical officer of health he had found it not a bad thing He related instances of understanding sympathy in his work as medical officer which he had received from a check-weighman who was at that time the chairman of his health committee

Dr W G WILLOUGHBY said that it had been a very great honour to be made president-elect of the British Medical Association, the more so because the nomination was made unanimously on a ballot vote by his Eastbourne colleagues, not one of whom, with the exception of his assistant, was in the public health service He was not inclined to lay too much stress on the fact that it was the first time a medical officer of health had been chosen In the first place, the society was not more than half as old as the British Medical Association, and the private and other practitioners in the latter body had long been the leaders in preventive medicine Indeed, the part of the general practitioner in that field was often overlooked It was largely in the treatment of children that preventive medicine could be exercised, so as to prevent troubles arising in later life, and here the private practitioner had abundant scope He referred with gratification to the fact that the British Medical Association was ably represented on the council of the Society of Medical Officers of Health, and the society equally ably on the Association's Council A great deal was heard about "encroachments," on which subject he had had a discussion with the general practitioners in his district He had come to the conclusion that if he and his assistant had at times encroached on their preserves, they were constantly encroaching upon his It was very usual for his meals to be interrupted by a telephone call from a practitioner asking him to provide some kind of help for his patient In his district at least they had come to the conclusion that there was no such thing as encroachment, but, on the contrary, a great deal of mutual assistance He had been himself a general practitioner before becoming a medical officer of health, and he hoped to do his share with the other members of the Council of the British Medical Association in representing the whole profession of the country

The final event of the evening was the presentation, actually of a handsome piece of silver plate, and prospectively of a motor car, to Mr G S Elliston, executive secretary of the society from 1919 to 1930 Dr G F BUCHAN, in making the presentation, said that when Mr Elliston took control of the society it numbered only 700 members, now it numbered 2,000, and the financial position, which was then insecure, was now very sound This position was due, as also were the friendly relations existing with other organizations, largely to Mr Elliston's influence

RESEARCH IN MENTAL HOSPITALS.

As in previous years, the second volume of the annual report of the Board of Control[1] contains an account of the research work undertaken in various mental hospitals during the past year For the most part, this research consists in the investigation of such pathological changes as appear to have etiological significance in the psychoses, but several reports deal with investigations of diseases accidentally associated with mental disorder—for example, the typhoid-dysentery group—while others are mainly concerned with the effect of treatment, especially in general paralysis

Significance of Pathological Changes

Studies carried out under the auspices of the Joint Board of Research for Mental Diseases of the City and University of Birmingham have been directed towards investigating the etiology of and primary changes in chronic disease, especially in the neighbourhood of the brain Post-mortem examinations have confirmed previous findings of a large proportion of cases with macroscopic changes in the sphenoidal sinuses and antra Sensory disturbances, whether perceived by the subject as of an ordinary character or as an hallucination, have been constantly searched for and used as an indication of the presence of septic disease processes in the head It is claimed that the results prove that the vast majority of so-called olfactory hallucinations are true cacosmia due to nasal disease

The oxygen capacity of patients' blood has been compared with the total haemoglobin content in order to find out whether forms of haemoglobin, useless for respiratory purposes, occur It has been shown that anoxaemia may give rise to mental derangement, and it is thought that similar processes occurring at various ages from embryonic to adult life, and variations in the duration of the condition, are responsible for different psychiatric types of mental disorder Work undertaken at the Cardiff Mental Hospital includes the investigation of the changes in carbohydrate metabolism occurring in psychotics The results so far indicate the close relationship between the sustainment of hyperglycaemia incurred by the ingestion of glucose and the emotional tension of the patient

The report from the London County Mental Hospital, West Park, includes an account of an investigation into the distribution of chlorine in the blood and urine in certain types of mental disorder Following on the increased respiratory ventilation after waking in the morning, the normal person shows an increased output of chloride in the urine In the psychotic patients examined there was a varying degree of retention of chlorides over the same period, associated with a varying degree of defect in respiratory regulation In normal persons exercise appears to have no effect on the distribution of chloride between plasma and corpuscles, while in katatonic dementia praecox the same amount of exercise causes a decrease in the acid load of the corpuscle owing to a decrease in alveolar CO_2 tension

The relation between the cause of death to the type of insanity is considered in the report from the Cheshire County Mental Hospital, Parkside, Macclesfield A striking contrast is furnished by comparing the number of schizophrenics dying from heart disease and chronic nephritis with the number of melancholics dying from the same condition—5 out of 68 schizophrenics and 41 out of 67 melancholics Uraemia as a cause of death in the insane has been investigated at the East Sussex County Mental Hospital Renal failure at death occurred in 80 per cent of cases Post-mortem examination of the cerebro-spinal fluid revealed a very high percentage of normally high urea contents, and this has definitely been shown not to be due to decomposition changes Further investigation is in progress with regard to the renal function during life

At the Essex County Mental Hospital blood cholesterin has been found to be raised in dementia praecox and manic-depressive insanity, to a lesser extent in other psychoses, but not in imbecility States of confusion, excitement, and depression are accompanied by a fall in blood cholesterol, with a return to the former high content as the acute mental state disappears At St Andrew's Hospital, Northampton, a study has been made of gastro-intestinal focal infection in relation to oral sepsis By employment of anaerobic technique oral sepsis may be traced through the digestive tract

The above-mentioned investigations are merely a selection from reports too numerous to cite in detail They are evidence of the difficulty and obscurity of the problems awaiting solution, and of the thoroughness with which these are being examined

Treatment of General Paralysis

The treatment of general paralysis of the insane form the principal communication from several mental hospitals. The treatment of general paralysis by induced malaria has been continued at the West Riding Mental Hospital Wadsley, and is considered valuable. Treatment of this disease by Ducrey's bacillus has been carried out at the Norfolk County Mental Hospital. A vaccine of Ducrey bacillus has the property of producing a high temperature and a "fever" is obtained without the physical discomforts and risks attendant on malarial therapy. The results so far are satisfactory. At the Maudsley Hospital tryparsamide has been found to be a most valuable drug in the treatment of general paralysis. It forms a valuable substitute for fever therapy where the latter is contraindicated, but the most effective mode of treatment is considered to be a combination of tryparsamide with fever.

ORGANIZATION OF PHYSIOTHERAPY

MEETINGS IN LONDON

A MEETING of between thirty and forty practitioners interested in physiotherapy was held in London on November 14th Sir LEONARD HILL presiding to consider the formation of a society of physiotherapy. Letters supporting the proposal were read from two medical members of Parliament and from a dozen others, practitioners of physiotherapy.

The CHAIRMAN said that many of those present must have received invitations to a meeting to take place on November 17th with a view to forming a society on another basis. There seemed to be no reason why the two parties independently advocating the formation of a society should not come together as one.

Dr R. KING BROWN, the honorary secretary, made a statement on the subject of the *British Journal of Actinotherapy and Physiotherapy*, of which he is joint-editor and which has apparently given rise to objection in some quarters. The suggestion that the new society would be run by the *Journal* did not contain a word of truth. The *Journal* would be run by the society. The periodical had no connexion whatever with the trade. It was of course a commercial *Journal* and it accepted advertisements as all journals did, but it received no subsidy from the trade or from any trade association.

Dr A. EDINOW moved that a society of physiotherapy be constituted. Those interested might have joined up with the Electro-Therapeutic Section or the Royal Society of Medicine or with the British Institute of Radiology, but in neither he thought would they have received the consideration which their specialty deserved. The resolution was seconded by Dr W. A. TROUT and supported by Dr FORTESCUE FOX and others. The CHAIRMAN read a note from Sir Thomas Horder who had been present in the earlier part of the meeting wishing the movement success.

Sir ROBERT STANTON WOODS urged that action should be held over until the meeting of November 17th to which he thought all present had received invitations and which he hoped they would attend in view of the great desirability of going forward unitedly and not in two camps. This view was supported by Dr E. P. CUMBERBATCH. On the other hand Dr MURRAY LEVICK thought that if the meetings were amalgamated the present movement which had taken the initiative would lose its identity. Dr W. J. O'DONOVAN spoke in the same sense.

Dr Edinow's resolution was then put and carried without dissent and it was further agreed that the name of the society should be The Society of Physical Medicine and that Dr Edinow, Dr O'Donovan, Dr Murray Levick, Dr Kerr Russell and Dr King Brown with Sir Leonard Hill acting as chairman should form a small committee to draw up a constitution. The CHAIRMAN closed the meeting by remarking that they must see what happened at the meeting called for November 17th and find out whether it was possible to bring about union. He added that he and those associated with him were not out to form a society on their own if they could possibly get union.

A meeting to consider the question of forming a society of physiotherapy was held at the rooms of the Medical Society of London on November 17th with Professor W. E. DIXON in the chair, between fifty and sixty were present.

The CHAIRMAN gave an account of the origin of the proposals and said that matters had taken a somewhat different turn owing to a letter from Lord Dawson of Penn who earnestly advocated that those interested should endeavour to find adequate expression for themselves within the Royal Society of Medicine.

Lord DAWSON made some remarks in support of this view. He agreed that those who practised physiotherapy had not at the present time an adequate organization or means of exchanging ideas and he thought such an organization should be provided. But the great advantage of coming into an organization where they would rub shoulders with those pursuing other branches of medicine had to be remembered. Such a body as the Royal Society of Medicine gave support to each of its constituent Sections and exercised a healthy restraint without interfering with their freedom. He begged them to intend to make a strong endeavour to come within the walls of the Royal Society of Medicine. This was not the time to try to start new organizations. On the subject of education and the recognition and examination of technical assistants a Section of the Royal Society of Medicine would be able to make strong recommendations in suitable quarters.

Sir WILLIAM WILLCOX expressed sympathy with Lord Dawson's point of view but said that there was a feeling that the Royal Society of Medicine rather shelved discussion on the larger or more public aspects of a subject.

Sir LEONARD HILL said that two meetings had been held for a similar purpose by another group which had interested that he should preside, and at the second meeting it was agreed to form a Society of Physical Medicine. At the same time he was all out for unity, he fully agreed that it would be a mistake to form two separate societies. As to joining up with the Royal Society of Medicine he saw both advantages and disadvantages.

Dr FORTESCUE FOX pleaded for a broad basis embracing the whole scope of physical medicine; physiotherapy would not do. He also recalled an occasion on which the council of the Royal Society of Medicine had declared that questions of medical education were outside its scope although one of its Sections had felt strongly on the subject. Dr W. J. O'DONOVAN urged that a separate society should first be formed that it should be all embracing and should claim later on an absorption into the Royal Society of Medicine. Dr A. EDINOW pleaded for general support for the new body which had just been constituted. Dr KING BROWN described the formation of that body, remarking that many practitioners did not wish for full membership of the Royal Society of Medicine. He agreed that it would be absurd to form two societies and invited everybody present to join the one which had been formed. Sir R. STANTON WOODS outlined the history of the meetings already held, urged unity and said that he did not propose to join the society formed last week. Dr W. KEPP RUSSELL said that most of those present were already members of the Royal Society of Medicine and the proposal to form a new body was largely the result of dissatisfaction with that Society.

Dr STANLEY MELVILLE supported the view that action should be taken through the Royal Society of Medicine and Sir WILLIAM HALE WHITE spoke to the same effect but Dr M. B. PAY criticized the policy of the Society's council remarking that the Section of Balneology had not been allowed to take any action in the formation of a spa practitioners group. Lord DAWSON said that the policy of the Royal Society of Medicine was not unmutable; the sensible thing to do was to try to alter what was bad and not weaken the work by multiplication of organizations. In reply to a question by Dr C. B. Heald Lord Dawson assured the meeting that a committee which it appointed would have a sympathetic reception from the Royal Society of Medicine. Dr HECTOR MUNRO deprecated the formation of a new society and suggested three Sections in the Royal Society of Medicine for electrotherapeutics for radiology and for other branches of physical medicine.

The CHAIRMAN (Professor Dixon) said that Lord Dawson had converted him to the idea of forming a Section of the Royal Society of Medicine.

Lord DAWSON then moved and Dr HECTOR MUNRO seconded:

> That a committee representative of the various aspects of knowledge and of opinion be constituted in order to explore a plan of forming an adequate representation of [illegible] therapy within the confines of the Royal Society of Medicine.

As the result of some criticism by Dr F. Vanderpant the proposers agreed to add the word "and" in the event of failure to explore other avenues" and in this form was carried unanimously. The chairman and Sir Leonard Hill were appointed as the nucleus of a committee to add to their number that they would invite others to join them in forming a committee to study the possibilities and to report at a later date.

PHYSICAL FITNESS OF MOTOR DRIVERS.

THE B M A AND THE REGULATIONS

IT IS common knowledge that the Draft Regulations under the Road Traffic Act—known as the Motor Vehicles (Driving Licences) Regulations, 1930—which come into force on December 1st, have been the subject of detailed discussion between the Minister of Transport and representatives of interested bodies, including the British Medical Association Certain statements have appeared in the lay press from which it might be assumed that the standards of physical fitness imposed by these Regulations on the candidates for driving licences are in accordance with the recommendations of the Association Such an assumption would be ill founded The special Committee appointed by the Association in July, 1929, "to investigate and report upon the problem of the medical and physical fitness of drivers of motor cars, and to suggest what tests might be recommended for adoption by local authorities," made certain recommendations as to standards of fitness and the methods of imposing such standards, which were approved by the Representative Body in July, 1930, and conveyed to the Minister in a letter, which is printed in full below

The recommendations of the Committee were designed to ensure that so far as possible no person suffering from any disease or disability likely to make his driving a source of danger to the public should be granted a licence, while, on the other hand, no applicant, whatever his disability, should be unnecessarily precluded from driving, whether by conscientious scruples or by any defect which could be adequately compensated by artificial aid or personal care and skill They postulated provision for medical examination as an essential part of the machinery for deciding those cases of doubtful capacity covered by the third and *fourth items in the draft form of application for a licence* In the opinion of the Committee, it is inequitable in such cases to place upon the applicant the onus of a decision as to the degree of incapacity likely to entail danger, while there are obvious practical limits to the utility of a road test as a measure of some forms of disability The omission from the Draft Regulations of any provision for medical examination leaves the onus of decision as to mental and physical fitness for driving on the candidate, who will himself have to decide what medical advice, if any, he requires to enable him to declare that he is not suffering from any disease or disability which would be likely to cause the driving by him of a motor vehicle to be a source of danger to the public The importance of his decision in this connexion is obvious, for the disabilities which it covers must be taken to include such conditions as general paralysis of the insane, gross heart disease, and marked restriction of the field of vision

The difference between the two schemes is clear, and the British Medical Association is in no way committed to approval of that adopted by the Minister Its advice was, however, sought as to the best means of defining the standards acceptable to the Ministry for the purposes of the scheme actually adopted and subject to its limitations, and the fact that the scheme itself was not in accordance with its original recommendations was naturally no bar to rendering technical assistance of this kind It should, however, be clearly understood that the collaboration of the Association in formulating the Regulations was confined to determination of their form rather than their content

The original recommendations of the Association are set out in detail in a letter addressed by the Medical Secretary of the Association to the Ministry of Transport on February 21st, 1930, as follows

The Association's Letter

The Council of the British Medical Association has had under consideration the Road Traffic Bill, which is at present before the House, and I have been instructed to convey to you certain suggestions and recommendations which the Council believes will be of assistance to the Ministry in connexion with the Regulations which will have to be drawn up as soon as the bill becomes law

The Council is, in the main, in substantial agreement with the bill itself, but would suggest an addition to Clause 22 which it trusts the Minister will see his way to propose himself during the Committee stage, or to accept as an amendment if such be moved when the particular clause is under discussion The suggestion which the Council wishes to make is the desirability of investigating the physical and mental condition of the driver as well as the condition of the vehicle in every case in which an inquiry may be made under Clause 22 of the bill

With regard to the Regulations the Council was faced at the outset by the fact that the information which can be required from a candidate for a licence should be such as the candidate is normally in a position to supply without having recourse to expert assistance, and such information is necessarily extremely limited The Council is of the opinion (1) that the required declaration should be in general terms to the effect that the candidate to the best of his belief does or does not suffer from any one of a specified list of disabilities or any other condition which would be likely to render his driving a source of danger to the public, and (2) that the list of disabilities specified on the form of application should be in simple and popular language and calculated to convey to the average candidate a clear idea as to the general nature of the disabilities which should be declared, and that it should not purport to be an accurate description in scientific terms of the exact conditions which should be considered a disqualification for obtaining a licence A declaration of this nature would seem to be covered by the terms of Clause 5 (1) of the bill

It follows from the nature of the declaration recommended by the Council that this declaration cannot in itself afford sufficient ground for a final decision as to the qualification of a candidate to hold a driver's licence The bill provides that, except in the case of such diseases and disabilities as may be prescribed as an absolute bar, an applicant suffering from any of the specified conditions shall be at liberty, on payment of a prescribed fee, to claim to be subjected to a test as to his fitness or ability to drive a motor vehicle of the class or description for which he desires a licence, and on passing the prescribed test shall, if he is not otherwise disqualified receive a licence of the class for which he has shown himself to be qualified

The Council is of the opinion that while certain conditions should undoubtedly constitute an absolute bar to the issue of a licence, their existence can in the majority of cases only be satisfactorily determined by tests, and that provision should be made where necessary for both a medical examination and a practical driving test With the exception of total blindness and epilepsy the Council is definitely of the opinion that the average candidate cannot be expected to make a declaration in such a form as to decide the point at issue If, therefore, certain conditions are to constitute a statutory bar to the issue of a licence, their existence in the individual case must in general be determined by reference to a competent medical opinion, and not by the bare statement of the applicant

The reason for requiring a medical examination is obvious, since there are diseases and disabilities (notably general paralysis of the insane) which, whilst they may at any time render the applicant totally unfit to drive, would not necessarily prevent him from passing satisfactorily any practical test of driving capacity

A practical test of driving capacity will, however, be desirable in many cases in addition to the medical examination, since care and skill in driving may be an adequate compensation for the presence of gross lesions which in themselves, and apart from the capacity for exercising such care and skill, might be taken as a disqualification

The Council recommends, therefore, that, whilst the declaration required from the applicant should be in general terms, more precise standards should be formulated for the guidance of the licensing authorities of the medical practitioners, to

whom the authorities should refer for examination applicants or drivers who appear to be the subject of any of the specified diseases or disabilities and also of the Courts with whom lies the ultimate decision in the case of an applicant who appeals against the refusal or revocation of a driver's licence. Such standards will also be of use to the private practitioners who may be asked by their patients as to the advisability of driving cars.

The Council desires to emphasize its opinion that deafness in itself should not be considered as a disqualification for driving, and that neurasthenia should be excluded from the list of specified conditions because in the case of the psychoneuroses there is either a complete inhibition against driving at all or the patient is able to drive in safety.

The Council considers that if and when a system of traffic control by colour signals is put into force the danger involved in the wide incidence of defect in colour vision should be met by the addition of adequate signals other than mere colour.

The Council is aware that numerous authorities on the Continent and in America carry out psycho-technical tests, but there is little or no evidence to show that these tests have any great practical utility. It considers that although further research on the subject would be of great interest, any general application of psycho-technical tests in this country is neither desirable nor practicable at the present time.

To sum up, the Council of the Association recommends:

1. That for the purpose of Clause 5 (2) (*b*) of the Road Traffic Bill the only condition for practical purposes which should be constituted an absolute bar to the issue of a driving licence is epilepsy.

2. That the following conditions as to disease or physical disability should be prescribed in the form of declaration contemplated under Clause 5 (1) and 2 (*b*) of the Road Traffic Bill:

- Very defective vision
- Mental disease
- Alcoholism or drug addiction
- Epilepsy
- Paralysis
- Liability to attacks of disabling giddiness
- Loss of foot or hand
- Gross stiffness of joint including the neck
- Gross heart disease

and that the applicant should be asked to state in as brief and simple a manner as possible whether or not he is suffering from any of the diseases or disabilities so specified; that any applicant declaring himself to suffer from any such disease or disability should be referred to a medical examiner who should after due examination recommend

(*a*) that the applicant should not be disqualified for holding a licence; or

(*b*) that the applicant should be subjected to a road test; or

(*c*) that the degree of disability is such that the grant of a licence should be refused.

3. That in reporting upon any person referred to him as above or under Clause 5 (4) of the Bill the medical examiner should have regard to the following standards:

	Degree of disability which would warrant examining practitioner recommending that licence should be refused.	Degree of disability which would warrant examining practitioner recommending a road test before licence granted
Very defective vision	Defects which cannot be adequately corrected by glasses or serious defect of the field of vision	Limitation of field of vision
Alcoholism or drug addiction	—	All cases
Paralysis — —	—	Paralysis of any description involving loss of full use of hand or foot
Liability to attacks of disabling giddiness	Ménière's disease, cerebellar tumour	—
Loss of foot or hand and gross stiffness of joints including neck	—	All cases
Gross heart disease ..	Angina pectoris, severe valvular disease, myocardial degeneration	—

4. That in the case of applicants for a licence in respect of a public service vehicle (Clause 72) the medical examiner's report should be on the lines of that at present in use by the Metropolitan Police Authority as follows:

[The details were here quoted.]

5. The Council is of opinion that the desirability of investigating the physical and mental condition of the driver as well as the condition of the vehicle should be considered in every case in which an inquiry may be made under Clause 22 of the Bill.

The suggestions contained in this letter are the result of the deliberations of a special Committee which was set up by the Council to consider the important problems involved. The constitution of this Committee was as follows:

Professor JOSEPH BARCROFT, M.A., F.R.S., Cambridge (Physiologist), *Chairman*.
Professor ARTHUR H. BURGES, M.S., F.R.C.P., Manchester.
Dr. C. O. HAWTHORNE, D.S.O., F.R.C.P., London.
Dr. H. B. BRACKENBURY, London.
Mr. V. BISHOP HARMAN, F.R.C.S., London.
Dr. F. H. BODMAN, Bristol.
Dr. CHARLES BUTTAR, Guildford.
Sir E. FARQUHAR BUZZARD, Bt., M.D., F.R.C.P., Oxford.
Dr. W. H. DAVIDSON, Birmingham (Medical Coroner).
Group Captain MARTIN FLACK, R.A.F.M.S.
Dr. P. G. GORDON, F.R.C.P.Ed., Bath (Psychologist).
Mr. E. L. PEARCE GOULD, F.R.C.S., London.
Mr. SOMERVILLE HASTINGS, M.S., F.R.C.S., London (Auralist).
Dr. H. L. HATCH, Pinner.
Sir JOHN PARSONS, F.R.S., F.R.C.S., London (Ophthalmic Surgeon).
Dr. F. A. POPPER, Exeter.
Dr. T. H. G. SHORE, F.R.C.P., London.
Mr. E. B. TURNER, F.R.C.S., London.
Mr. P. JEWETT VERRALL, F.R.C.S., London (Orthopaedic Surgeon).
Mr. V. E. WATERFIELD, F.R.C.S., Banbury.

In preparing its report this Committee had the assistance of the Secretary and Deputy Secretary of the Automobile Association, and their views are substantially in agreement with the Committee's findings.

Representatives of the Council would be glad to discuss any or all of the points mentioned with the Minister or his representatives at any time which is found to be convenient.

Terms of Regulation 5

The Regulation which deals with physical fitness of drivers and provides for road tests is as follows:

5.—(i) The diseases and disabilities in the case of which the applicant for a licence shall not be entitled to claim to be subjected to a test as to his fitness or ability to drive a motor vehicle under Subsection (2) of Section 5 of the Act shall be the following: Epilepsy; liability to sudden attacks of disabling giddiness or fainting; inability to read at a distance of 25 yards in good daylight (with the aid of glasses if worn) a series of six letters and figures in black on a white ground of the same size and arrangement as those prescribed for the identification mark of a motor car.

(ii) The fee to be paid by an applicant who claims under that subsection to be subjected to such test shall be ten shillings.

(iii) In order to pass such test the applicant for a licence shall prove to an examiner approved by the Licensing Authority his ability unaided to:

(*a*) Start the vehicle from rest so as to move away in a reasonably quick time and to maintain an accurate course;
(*b*) Turn right and left hand corners correctly;
(*c*) Stop the vehicle within a reasonable distance when travelling at various speeds (In the case of a motor vehicle to satisfy the examiner that in an emergency he will be able to apply the brakes promptly and effectively);
(*d*) Operate all controls with safety and with a minimum of moving from the driving seat;
(*e*) Give all recognized signals to other persons using the road and to traffic controllers in a clearly understandable manner (If owing to his disability it is impracticable or undesirable that he should give such signals by hand the vehicle must be fitted with a device or devices which in the opinion of the examiner will be satisfactory for this purpose);
(*f*) Except in the case of a motor cycle make the vehicle proceed backward for a reasonable distance, make a left and right-hand turn in reverse gear and bring the vehicle into an indicated position;
(*g*) Turn the vehicle round so as to proceed in the opposite direction in a roadway thirty feet in width;
(*h*) Stop, hold and start the vehicle on a gradient of at least 1 in 15, but not steeper than 1 in 10.

Generally the applicant shall satisfy the examiner that he is capable of driving a motor vehicle or a motor vehicle of the particular construction or design to which the application relates without danger to other users of the road

Declaration as to Fitness

Section C of the first schedule to the Regulations defines the terms of declaration of physical fitness to be made by the applicant for a driving licence It runs as follows

The applicant is required to furnish answers to the following questions by placing the word Yes or No in the space provided opposite each question

"1 Do you suffer from epilepsy or from sudden attacks of disabling giddiness or fainting?

"2 Are you able to read at a distance of 25 yards in good daylight (with glasses if worn) a motor car number plate containing six letters and figures?

"3 Have you lost either hand or foot or are you suffering from any defect in movement control or muscular power of either arm or leg? If so give particulars

I declare that I am not suffering from any other disease or disability which would be likely to cause the driving by me of a motor vehicle to be a source of danger to the public

[On the back of the declaration form is a note stating that if the applicant is in doubt as to the answer to be made either to Question 1 or to Question 2 he should obtain professional advice]

Scotland.

Rector of Aberdeen University

As briefly announced in last week's issue Sir Arthur Keith, M D LL D was elected on November 8th, Rector of Aberdeen University for the coming three years in succession to the late Earl of Birkenhead Sir Arthur Keith stood as a non-political candidate against Colonel John Buchan M P who was put forward by the Aberdeen University Unionist Association Sir Arthur is a native of Aberdeenshire and received his education at Robert Gordon's College, Aberdeen, and at Aberdeen University It is the first occasion in its history that Aberdeen University has had at the same time a Chancellor—Lord Meston of Agra and Dunottar—and a Rector who are both alumni of the University

Registration of Blind Persons in Scotland

A circular was issued on November 7th by the Department of Health for Scotland dealing with the registration of blind persons, and giving directions as to arrangements for their medical certification A copy of the central register of the blind, kept by the department, has been issued to all local authorities, containing particulars of individual blind persons already registered, including an occupational classification A form is appended to the circular upon which local authorities are requested to furnish information regarding blind persons in their areas as on April 1st, 1931, with a view to securing uniformity throughout the country The department suggests that every society dealing with the blind in any given area should maintain such a register on behalf of the local authority, and urges close co-operation between local authorities and local pensions committees It points out that some inaccuracy has been caused by the acceptance of certificates by persons other than ophthalmic surgeons, and by lack of uniformity in the interpretation of the standard of blindness The circular states that in the past year only 39 5 per cent of cases were certified as blind by ophthalmic surgeons 44 1 per cent were certified by local medical practitioners, 1 6 per cent according to other evidence, and in 14 8 per cent no particulars of certification were furnished A blind person is defined in the Act of 1920 as one "so blind as to be unable to perform any work for which eyesight is essential" The department considers that the most satisfactory arrangement for certification would be the establishment of regional clinics, all certification being conducted by ophthalmic surgeons The central register of the blind at April 1st, 1930, indicated that there were 8,897 blind persons in Scotland, representing 1 blind person to every 549 of the general population It is suggested that in areas where the incidence of blindness exceeds this ratio, re examination by a properly qualified person should be carried out

Training of Nurses

In an address on nursing services under the Local Government Act, delivered on November 14th, at a meeting held in Glasgow City Chambers, Dr A S M Macgregor, medical officer of health for Glasgow, said that this Act brought under a single administrative control three large groups of hospitals, with their associated medical and nursing staffs These were the general hospitals previously administered by the Poor Law, the hospitals for mental disease—formerly under district boards of control—and the hospitals for infectious disease, including tuberculosis already administered by the local authorities The Act also effected a union between staffs of health visitors required for education health service, maternity and child welfare services, tuberculosis, general sanitation, and other objects The local authority in Glasgow would have to deal with over 1,600 nurses, including trained nurses, and those in training There were about 3,000 beds in the voluntary hospitals, and approximately 8 500 in the hospitals administered by the corporation The latter included over 3,000 beds in mental hospitals, 1 500 beds for infectious disease, 1,400 beds for tuberculosis, and about 2,500 classed as general hospital beds The local authority was therefore closely concerned with the conditions of nursing service for a considerable variety of functions In the training of nurses at present each institution acted as an independent school, and qualified its own staff for admission to the general or the fever nursing registers Training in special hospitals, such as those for the treatment of tuberculosis, was not recognized as forming part of the curriculum for registration Many nurses took both general and fever training certificates involving at least six years' training If a nurse desired a certificate in midwifery, another six months was required, and still another six months was necessary if a nurse was to become a health visitor This curriculum was too long for an all-round comprehensive training In the United States a nurse might obtain a wide training within periods varying from three to five years The problem in that country was simpler, however, because training institutions for nurses were affiliated with medical schools and the large hospital systems in serving a variety of purposes made a wide experience easier to obtain The provision of a considered scheme for nursing services in this country demanded early solution, and would require consideration from three points of view—namely, the effect on the individual hospital, the avoidance of a training which might lose sight of essential principles, and the facilities and status of the various institutions providing parts of the curriculum

England and Wales.

Halley Stewart Lectures

Continuing his Halley Stewart Lectures—referred to in the *Journal* of November 15th (p 841)—Sir George Newman dealt with the subject of "Modern collective humanism at work" The increase in expenditure, he said, from 20 millions in 1891 to 322 in 1928, indicated not only the magnitude of the growth of the social work of the State on behalf of the individual, but also made it necessary to ask if this vast outlay was proving an undue burden upon revenue and industry, and if it was yielding commensurate results To maintain our health and life as a nation, to develop our capacity, creativeness, self-reliance, independence, and even security, was good and profitable statecraft, but to do so much for the individual that he became lazy, indifferent, dependent, and parasitic, was evil and wasteful The lecturer then discussed in detail four aspects of the public health services of a modern State—namely the saving of infant life, the medical service on behalf of maternity, child welfare, and national health insurance An organized service of medicine, he said

had manifestly given the nation immense advantages in regard to an organized and regulated medical profession an improved medical education a hospital and dispensary service for the poor health reform of the factories the defeat of pestilences the care of maternity, child life and the school child, a system of health insurance for 14 million persons, and an ever-expanding means of medical research and discovery In view of the fact that the health insurance system involved intimate relations between 15,000 doctors and 14 million persons criticism and complaint was not remarkable since the scheme was still incomplete and had many imperfections The vital questions were first whether the present scheme was better than the old contract medical practice and secondly whether the patient was getting better treatment than formerly He claimed that the scheme was beyond doubt an immense improvement on previous arrangements, and the treatment provided very much superior Moreover progress was being made every year It was important, however to keep steadily in mind that the appropriate organization of medical services must never be allowed to convert the medical profession into a branch of the Civil Service

The fourth and last lecture was entitled 'Gains and losses in national health needs of the future" Sir George Newman first indicated the chief milestones in the modern advance of medicine such as the prevention of scurvy, the beginnings of immunity anaesthesia, causes of infective disease, antiseptic surgery and the invention of instruments of precision in diagnosis and treatment On the credit side the expectation of life at birth had increased by eighteen years since 1838 From 1838 to 1854 the expectation of life at birth was 40 years, it was now approximately 58 Another gain had been the elimination of pestilences such as leprosy plague, famine pestilence, sweating sickness typhus and cholera On the whole he considered that the resistance of the community was steadily increasing due partly to immunization, but mainly to improved nutrition It appeared that life was more comfortable physically and that there was less suffering owing to the applications of modern medicine Further life was more tolerable and happier there was increased capacity, though not always accompanied by increased output The great improvements in childhood in factory betterment and in housing had played their part On the other hand England had failed to control cancer influenza, digestive disorder, rheumatism and mental disease The public health services were saving life at an extraordinary rate which naturally and inevitably included saving enfeebled impaired, and diseased lives Moreover the birth rate was highest in those classes of the community that were physically the least virile The results of this change though not excessive or in any way alarming were fairly definite Many young women were coming into maternity with lessened stamina the pre-school child still remained defective some of the school diseases still persisted, part of the excessive sickness claims were due to this impaired physique and certain diseases were on the increase Again we had failed to educate the people in health the opportunity for wise and constructive teaching of hygiene in schools was largely neglected, and quackery food stunts indiscriminate artificial contraception and sterilization were looked to with more regard than they deserved

Radium in Surgery

A meeting of the Manchester Medical Society was held on November 5th when a paper on radium in surgery was read by Mr H S Souttar surgeon to the London Hospital He recalled that although radium was discovered thirty years ago it was only within the last few years that it had become of general use in surgery The beta waves were caustic in their effect and must be eliminated by screens of platinum and silver The gamma rays had a selective action on carcinoma and when suitably applied were capable of destroying the cells of a carcinoma without any corresponding injury to the connective tissues Gamma rays appeared to affect the cell at the moment of its division destroying the chromatin which at that moment was in a peculiarly sensitive state The work of Regaud on the seminiferous tubules in the rat was a conclusive proof of its action It was thus essential that a malignant tumour should be exposed for a sufficient time for every cell to have the opportunity of dividing In the clinical use of radium one of the chief objects in view was to obtain a perfectly uniform irradiation, both of the tumour and of the whole lymphatic area associated with it In Mr Souttar's opinion this was best accomplished by the introduction of seeds containing minute amounts of radon and suitably screened These seeds could be introduced in very large numbers by means of a special instrument which controlled their position with great precision Tumours varied greatly in their sensitivity to radium Epitheliomas of the skin and of the mucous linings of the cutaneous orifices were highly sensitive, especially if of the basocellular type Glandular tumours such as carcinoma of the breast were not so sensitive but could in most instances be made to respond Sarcomas were variable, those arising from bone being highly resistant Although it was still too early to form definite conclusions Mr Souttar was greatly impressed by the results so far obtained and thought that radium would ultimately replace surgery over a very large field of malignant disease

Birmingham Dental Hospital

At the prize distribution of the school at the Birmingham Dental Hospital Mr Malcolm Knott chairman of the surgical committee announced that enlargement of the institution was contemplated in view of the continued increase in the number of patients The present students were receiving an exceptionally valuable clinical education in administering anaesthetics and operating under anaesthesia Mr Knott maintained that dentistry had not yet become an overcrowded profession, since so many openings had come into existence for dental work in connexion with school clinics the fighting Forces, and large industrial concerns Sir Frank Colver, who presented the prizes dwelt on the professional and clinical aspects of a dental career He urged the students to pay attention to the scientific side of dentistry in order that advances might be made in knowledge

Correspondence.

MENTAL TREATMENT ACT APPROVAL OF MEDICAL PRACTITIONERS

SIR,—In your issue of November 8th you were good enough to publish a notice issued by the Board of Control in the following terms

> Medical practitioners who desire to be approved by the Board of Control for the purpose of making recommendations in respect of voluntary patients under 16 years of age—Section 1 (3) of the Mental Treatment Act—and temporary patients—Section 5 (3)—can obtain the necessary form of application by writing to The Board of Control Caxton House West Tothill Street London S W and marking the envelope M T D in the top left hand corner As the Act comes into operation on January 1st next intending applicants should write for this form immediately The Board cannot entertain applications for approval from medical practitioners of less than five years standing on the *Medical Register*

A similar notice was printed in other journals and newspapers, but up to the present a very small number of applications have been received from medical practitioners for approval under the Act It will of course be appreciated that the operation of Sections 1 (3) and 5 (3) of the Mental Treatment Act as from January 1st next will be seriously handicapped unless there is a sufficient number of medical practitioners approved by the Board for the purpose of signing recommendations under these sections In particular a temporary patient cannot be received for treatment under Section 5 unless the recommendation has been signed by a medical man who has been approved by the Board of Control for the purpose and if in any area there are no practitioner so approved the medical profession may find themselves in difficulty in securing that their patients shall have the advantage of treatment under those provisions.

It is therefore a matter of urgent importance that an adequate number of medical men throughout the country should be approved, if possible, before January 1st next, and the Board would much appreciate your assistance if, by publishing this letter in the columns of the *British Medical Journal*, you could bring the matter to the notice of the medical profession

Perhaps I might repeat, in conclusion, that medical practitioners seeking approval should write to the Board of Control, Caxton House West, Westminster, S.W.1, for an application form, and should mark the envelope "M.T.D." Applications can only be considered from practitioners of at least five years' standing on the *Medical Register*.—I am, etc.,

Board of Control, Westminster, S.W., Nov. 13th — L. C. BROCK, Chairman

TEMPORARY TREATMENT WITHOUT CERTIFICATE

SIR,—In reply to Dr. Dillon (November 15th, p. 843), the Mental Treatment Act, in my opinion, means what it says. A "temporary" patient is "incapable of expressing himself as willing or unwilling to receive such treatment." If a patient is capable of expressing "unwillingness," then he must be certified to enter an institution. I write as a member of the Parliamentary Committee which considered the Bill.—I am, etc.,

House of Commons, Nov. 15th — A. VERNON DAVIES

SIR,—Our Division recently discussed the new Mental Treatment Act, and the points raised by Dr. Dillon in the *British Medical Journal* of November 15th; there does appear to be a little confusion as to the correct procedure.

One expert considered that a patient should [illegible] Sir Art[illegible] mitted to a mental hospital without certification [illegible] Colour[illegible] ital illness was of such a nature that there was [illegible] real probability of an improvement in a reasonable time, even if the patient was incapable of expressing himself as willing or unwilling to receive such treatment. Another expert pointed out that the patient must be likely to benefit by temporary treatment. In the opinion of certain practitioners, every case of mental illness sent to a mental hospital would be expected to benefit by proper supervision and treatment, even though the disease might be of a progressive nature, and therefore all cases should be admitted on the certificates of two practitioners without recourse to a justice's order. Further information on the matter is most desirable.—I am, etc.,

St. Albans, Nov. 15th — SIDNEY CLARKE

SIR,—The new Mental Treatment Act, Section 5, states that a patient, in order to be eligible for a recommendation for temporary treatment under it, shall, among other requirements, be incapable of expressing himself as willing or unwilling to receive treatment, and a statement to such effect has to be made and signed by both the practitioners making the recommendation. Dr. Frederick Dillon in your last issue doubts whether this section means what it says, and desires an authoritative ruling on the point.

Section 16 of the Act states that where a person has signed such a recommendation he shall not be liable to any civil or criminal proceedings on the ground of want of jurisdiction or on any other ground unless he has acted in bad faith or without reasonable care, surely this implies that if the practitioners, after a thorough psychological examination, come to the decision that the patient is insane, they can safely sign the recommendation. The object of this section of the Act is to obviate the certification of persons as of unsound mind if they are curable cases of mental disorder which are bereft of the power of volition.

Nowadays it is customary to admit almost any case as a voluntary boarder if the patient is able to sign an application form; this will be continued under the new Act, and it is probable that when this Act becomes known many cases which are now certified as of unsound mind will be received under Section 5, so great is the objection to certification among general practitioners and the public. Certification under the principal Act will only be resorted to if the patient does not recover within the time limit. An authoritative ruling on the meaning of the sentence "incapable of expressing himself as willing or unwilling" can only be afforded by the Law Lords; till then the practitioner will have to interpret the sentence to the best of his ability.—I am, etc.,

Darlington, Nov. 17th — L. HARRIS-LISTON

DIATHERMY ENUCLEATION OF THE TONSILS

A Warning

SIR,—I have reason to believe that a number of medical men are practising removal at one sitting of the whole or a large part of the tonsil by means of diathermy. That is to say, they amputate or enucleate with a diathermy electrode in place of the old-fashioned guillotine or dissector.

Now this is not the place to enter into a full discussion on the subject, particularly as I have already done so at some length in my book on *Diathermy*.[1] But I feel it my duty to issue this warning that extensive or complete diathermy removal of the tonsil may be followed by severe haemorrhage during the separation of the sloughs, a week or two after the operation. In these circumstances control of the bleeding is very difficult, and the patient may become exsanguinated.

As I have pointed out elsewhere,[2] if diathermy coagulation is to be used for removal of the tonsils, the operator should confine himself to very modest advances, and should not endeavour to make spectacular changes. In a word, if enucleation at one sitting is desired, the operation is much more safely performed by the ordinary dissector or guillotine, bleeding points being secured by ligature, as in any other surgical operation. To do otherwise is to run a serious, and if I may say so, after this letter, an unjustifiable risk.—I am, etc.,

London, W.1, Nov. 14th — DAN MCKENZIE

COLLAPSE FOLLOWING ANAESTHETIC

SIR,—Some may be surprised that I should be writing on this subject, but as I had the following experience I record it in the hope that it may be of assistance to others situated as I was.

The patient was a girl aged 10, and the operation was a simple appendectomy. Anaesthesia was induced with a small amount of chloroform and ether and then open ether was used. There was no crying or struggling. The operation was completed without incident and the child *put* back to bed. The *cough reflex had returned* and all seemed to be going well. Soon after I went in to see the child. I observed that the breathing was shallow and she was pale, the pulse rate was about 130. Gradually the pallor increased and the respiration became more shallow, when suddenly it ceased, the teeth were clenched and the limbs flaccid. Sitting down on the bed I lifted the child out of bed until her head was hanging perpendicularly downwards, and instantly a bright colour returned to the cheeks and some clear fluid ran out by the side of the clenched teeth—this was evidently from the pharynx and due to failure of the swallow reflex. There was no sickness or sign of spasm of the diaphragm. Respiration at once returned. I laid her back in bed, when a few minutes later the same cycle began again, the respiration becoming increasingly shallow. On this occasion I did not wait for the collapse. Again I placed her with her head downwards and as on the former occasion there was instant return of the colour and the breathing, the teeth were still clenched, but there was no fluid from the mouth on this occasion. Once again I laid her back in bed, when gradually the failure began again. After this third time reflexes all returned and consciousness gradually became established. The third attack was witnessed by the anaesthetist and the child's medical attendant, who had been summoned. There was some vomiting later and the pulse rate remained about 130 for eighteen hours, when it steadily came down and she made an uninterrupted recovery. The chest was x-rayed, but nothing unusual was to be observed.

The child has always tended to develop acidosis, and had had a large dose of glucose the night before and some hours prior to the operation. The gradual cessation of the respira

[1] *Diathermy Medical and Surgical in Oto-Laryngology*. The Anglo-French Library of Medical and Biological Science. London, 1930.
[2] Gradual Diathermy Destruction of the Faucial Tonsils. *Proc. Roy. Soc. Med.*, Section of Laryngology, vol. xxiii, September, 1930.

tion with pallor was clearly due to some change in the central nervous system, and the instant return of respiration, together with the bright colour, when the child's head was allowed to fall forward would strongly point to fall of blood pressure being an active factor.—I am, etc.,

London, W.1, Nov. 15th. MAURICE CRAIG

AVERTIN ANAESTHESIA

SIR,—The correspondence in your columns between Sir Francis Shipway and Dr. Parsons on the subject of avertin has interested me from the surgical standpoint, as I have been constantly using this drug for two and a half years in my surgical practice. I saw its use in Berlin three years ago, and, so far as I know, its properties as a general anaesthetic, especially for "routine work," were never claimed. Dr. Parsons states: "If avertin has to be given along with other anaesthetics the principal object of its use for routine work has disappeared," and that "if it has to be given in conjunction with another anaesthetic it ceases to be of primary importance." If Dr. Parsons holds this view, he is in danger of being criticized as showing a lack of knowledge of its clinical properties. Avertin is a powerful amnesic, and as such we are rid by a very safe means, at the start of psychic shock, *a very important factor to surgeon and patient alike*. The second, and equally important, factor is that by its use other drugs necessary to complete anaesthesia can be used in amnesic dosage, which avoids their inevitable toxic effects following major operations in which they are used alone.

Avertin combined with other drugs which are anaesthetics but which, superimposed in amnesic doses, give a complete surgical anaesthesia, is the ideal for the surgeon. With gas and oxygen, as I saw it used by Sir Francis Shipway at Guy's Hospital, it was a boon to the surgeon and a real delight to the onlookers. With very light ether (amnesic dosage), infiltration anaesthesia, or spinal anaesthesia for major operations in the vicinity of the diaphragm, its use is a godsend. In my own surgical practice during the past two and a half years I have used avertin in combination with other drugs which are not in themselves anaesthetics, but rather amnesics, and I have witnessed a big fall in my mortality rate. This speaks for itself.—I am, etc.,

Bradford, Nov. 10th. BASIL HUGHES

INDICATIONS FOR PERFORMING WILDE'S INCISION

SIR,—I have to thank Mr. Lavton for his reply to my letter on the above subject, published in your issue of October 11th.

As he begins by deserting his quondam leader, Sir William Wilde, whose procedure an incision at least an inch in length *through the periosteum*, was the original subject of discussion, I might leave the matter at that quite satisfactory point. Further, Mr. Lavton remarks that we should probably find ourselves in agreement after half an hour's talk on matters of detail—that is, in dealing with any individual case. This, if correct, would be all that I am concerned with, for good surgery consists in dealing in the best possible way with the patient in hand. I shall look forward to such a talk some day to reconcile *our differences but meanwhile the following are the most important points*.

Mr. Lavton considers that unless one of two very serious symptoms—rigidity of the neck and rigors—is present it is unnecessary to do an immediate mastoid operation. Now these are both late symptoms, and in the hospital which I have the honour to serve are very rare and practically only occur in cases sent in already suffering from mastoid disease. This is because at the first suspicion of bone disease the case is seen by an otologist who operates if he considers the bone is actually involved. These late cases are so rare in our practice that they do not materially alter the general proposition. Each of these should have been operated on long before. The patient would then have been better able to stand the operation.

My colleague Mr. William Wilson wrote in the Monsall Hospital 1926 report, reviewing several years' experience: "In no case have I opened the mastoid without finding gross septic infection. It seems to me that the only way to improve our results is by earlier operation. The danger of operation seems to be practically negligible." Further experience has confirmed this opinion, which has my complete concurrence. Very severe and even fatal cases arise in which neither of Mr. Lavton's "indications" is present.

The argument that unless we advise fever hospital authorities to send for us only in cases which present one of these two symptoms, lest they do not send at all, is to assess their degree of intelligence very low. Most enlightened authorities avail themselves of the special knowledge and skill of an otologist to help them in those surgical emergencies which are his special province. Other authorities should be encouraged to follow their example. Finally, to delay operation on the mastoid till indications of a spread beyond the mastoid are present is not to be in advance of the times, but to be well behind them.—I am, etc.,

Manchester, Nov. 15th. E. S. BURT HAMILTON.

RAYNAUD'S DISEASE

SIR,—Dr. Broadbent's memorandum on Raynaud's disease (November 8th, p. 778) would have had its *interest increased still further had he given not only the* systolic, but also the basic, blood pressure. In the *Journal* for August 23rd of this year I pointed out in my article on Raynaud's disease that the basic pressure was raised and as a result the blood found a difficulty in entering the vasa vasorum for the supply of the muscular fibres of the arterial wall. The patient referred to by Dr. Broadbent had a low systolic pressure, so that a slight raising of the basic pressure would have a disturbing influence on the ratio of the two pressures and bring about the same result as obtains when both pressures are raised considerably.

The point is important, as I have found that the use of parathyroid has a beneficial result in a large proportion of all cases where the basic pressure is raised. This is especially so in cases of rheumatic fever which occur in children whose food has contained too little lime. Such children have unstable constitutions and their blood pressures are quickly driven upwards by the introduction of poison into their blood. These children however respond readily to treatment in the form of lime together with parathyroid. In the October number of the *Medical Review of Reviews* I point out that in chorea the basic pressure is raised, and as a consequence the walls of the cerebral arteries are so affected as to supply the brain with blood in a somewhat erratic fashion, thus giving rise to the irregular movement. It is in these cases, however, that the giving of calcium and parathyroid is found to be so beneficial by reducing the basic blood pressure.—I am, etc.,

Swansea, Nov. 11th. G. ABBOTT STEPHENS.

MEDICAL RECIPROCITY WITH FRANCE

SIR,—In the period before the war, when it was necessary for France to guard herself from the invasion by Russians, Poles, and others, who were anxious to practise as medical men, the conditions for admission became very stringent. It was, moreover, practically impossible to discriminate between British medical men and those of other countries *in the treatment meted out. To-day things have changed*. The susceptibilities of Russia no longer need to be considered. It would be quite possible for France to treat directly with England and for the two countries to arrange new terms of medical reciprocity satisfactory to both.

At present it is necessary for a *British medical man to* pass the examinations for the Bachelor of Arts and of Science, which are preliminary to a medical student's career in France, then all the medical examinations, keep all the terms of residence, and secure from the Minister of Public Instruction a permit to practise in France. As against this a French medical man may practise in England if he passes only the final examination of the Conjoint Board. The Frenchman's task is easy, the Englishman's impossible. There is no reciprocity in it at all.

At the moment very few English practitioners are left in France. Yet they are wanted in Paris, on the Riviera

and would be welcomed in many health resorts, such as Aix, Vichy, Vittel, Brides, Evian, Plombieres, etc, which towns realize their value in attracting visitors It would not be necessary to press for full reciprocity, but an arrangement might be come to with the French authorities to admit up to, say one hundred British medical men who fulfil certain conditions, just as the Principality of Monaco allows four British doctors to practise there I cannot but think that the time is ripe and propitious for reopening the question of reciprocity, to which the French authorities are now in a position to give a favourable response — I am, etc,

Knowle Topsham Devon Nov 5th D W SAMWAYS

Obituary

DR ARTHUR RICHARD FREDERIC EXHAM, who died on October 19th in Market Drayton, at the age of 73 had been conducting his practice until within a few weeks of his death He received his medical education in Trinity College, Dublin, where he graduated M B, B Ch in 1879, and proceeded M D ten years later He commenced practice at Ashley in 1880, but removed in 1882 to Market Drayton, where he took a very active part in the social, as well as the medical life of the town and district He was surgeon to the Cottage Hospital, medical officer to the Post Office and various assurance companies certifying factory surgeon, and medical officer to the workhouse and provident dispensary He devoted fifty years of his life to the Drayton Union, and last March was presented with an inscribed silver salver by past and present guardians and officers as a token of appreciation of the services he had rendered For many years he assisted in the work of the local St John Ambulance Brigade, and in 1910 was prominent in the formation of its Market Drayton division He subsequently became superintendent and, later, district officer, and assistant commissioner In 1926 he was appointed commissioner for the No 7 District, including Shropshire and Hereford, and more recently still he was created Knight of Grace of the Order of St John of Jerusalem Joining the Market Drayton Volunteer Company in 1884 as a lieutenant, he continued until the ending of the Volunteer movement, when he retired with the rank of major, and was awarded the Queen Victoria decoration for long service On the outbreak of the great war he took command of the National Reserves in Market Drayton, and so continued until the armistice Dr Exham was chairman of the Shropshire Panel Committee for many years, a member of the Executive Committee of the Shropshire Branch of the British Medical Association, and a past-president of it also He was instrumental in forming four musical societies in Market Drayton, was a strong supporter of St Mary's Parish Church, president of the Market Drayton Book Society, a governor of the County Grammar School, a keen supporter of the University Extension movement, and a member for many years of the Market Drayton Cricket Club The funeral, on October 23rd, was widely attended by representatives of the societies in which Dr Exham had interested himself so actively

DR GEORGE WILLIAM PEAKE MAITLAND of Oldham, who died on November 7th, aged 54 was born in India in 1876, and was educated at George Watson's College, Edinburgh At Edinburgh University he had a distinguished student career during which he obtained medals in zoology, practical anatomy, and materia medica, and graduated M B Ch B in 1901 On going into general practice he acted as assistant for five years in Manchester, and then settled in Shaw, where he acquired a large practice His civil work was interrupted by the great war, and from the years 1915 to 1918 he was in the R A M C, serving with a temporary commission in Salonika and on the hospital ship *St Andrew*, being twice mentioned in dispatches He retired from the Army with the rank of captain, and again resumed practice, in which he was engaged at his death He was a member of the Oldham Division of the British Medical Association He leaves a widow and four daughters

The following well-known foreign medical men have recently died Professor HENDRIK ZWAARDEMAKER, aged 73, formerly director of the Physiological Institute at Utrecht, and author of a work on the physiology of smell and a textbook on otology, Inspector-General HEUYER, Commander of the Legion of Honour, aged 83, Dr SILVA, professor of ophthalmology at the Grenoble School of Medicine Dr GUSTAV RICHTER, professor of hygiene at Breslau, and author of several works on epidemic diseases Professor FRIEDRICH CARL HERMANN MATTHAEI, director of the obstetrical and gynaecological department, St George's Hospital, Hamburg, aged 66, Professor JOHANNES ILBERG of Leipzig, an eminent medical historian, who was awarded the Leibnitz medal by the Prussian Academy of Sciences in 1910, Dr EMILE VALUDI of Paris, formerly editor of *Annales d'Oculistique* Dr ROY, a Paris ophthalmologist Dr LUIS URRUTIA, an abdominal surgeon of Madrid, and Dr G B UCCHETTI, formerly professor of general pathology at Catania

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT]

THIS week the House of Commons discussed Palestine on Monday, read the Agricultural Land Bill a second time on Tuesday and went into Committee on the Education (School Attendance) Bill on Thursday Mr Culverwell, who had drawn a place in the ballot for Wednesday, gave notice of his intention to move that 'in order to restrict the increase and, if possible to effect a decrease, in the number of mental defectives, procreation by certain defectives should be prevented by such measures as segregation prohibition of marriage, or sterilization" This motion was unlikely to be reached, as others had precedence

Mr Freeman gave notice that on November 20th, he would ask the Minister of Health whether he would consider the amendment of the Medical Act of 1886 with a view to controlling the advertisements of drugs in medical papers

A Workmen's Compensation Bill dealing with the claims of injured men who are certified as fit for light work, received a second reading in the House of Commons on November 14th

Dr Drummond Shiels, Under Secretary for the Colonies, returned to the House of Commons on November 15th after illness Mr Lloyd George, in opening a debate on Palestine referred to the general satisfaction at Dr Shiels's return Dr Elliot also welcomed Dr Shiels, who he understood, had only left his bed that day members of the medical profession knew the strain that that involved

General Medical Service

Replying to Mr Freeman, on November 13th, Mr GREENWOOD said he had received a copy of the proposal of the British Medical Association for a General Medical Service for the Nation The principles on which it was based would receive careful consideration in any further public provision of medical service

Mental Treatment

Mr GREENWOOD said in reply to Mr Kinley on November 13th, that it was impossible within the limits of a parliamentary answer to describe the courses of treatment given in public mental hospitals, these varying according to the needs of the individual patient Until he learned of cases to the contrary, he could assure Mr Kinley that asylums in every case had a definite course of treatment to which patients were subjected Statutory provision already existed under which patients who no longer required institutional treatment could be discharged or released on trial in order to receive treatment by registered medical practitioners or by out patient departments set up by local authorities Patients could also be released from institutions on the application of their friends, provided medical attention was forthcoming outside

Psittacosis

Replying to Mr Clarke, on November 13th Mr GREENWOOD said the number of deaths registered in England and Wales during the period January 1st to September 30th in respect of which psittacosis appeared on the medical certificate as the cause was 15 There were no deaths recorded from this cause in 1927 or 1928, but there was one death in 1929 registered as due

to broncho-pneumonia and septicaemia which as the result of the inquiry made in accordance with the usual practice of the Registrar General was attributed to psittacosis

National Health Insurance

In reply to Mr Stephen on November 12th Mr W Adamson said he would send him a statement of the name of the medical referees for Glasgow under the National Health Insurance Act Their appointment was made with the approval of the Secretary of State for Scotland by the Department of Health for Scotland who selected doctors believed to be qualified in its opinion to act as referees The cost of the referee service was a charge on national health insurance fund There were no regulations for the guidance of medical referees under the Act Cases might be referred to the regional medical officer for his opinion either as to capacity for work or state of health at any stage of illness Medical referees merely expressed an opinion on the question of incapacity The decision whether benefit should be continued or stopped rested entirely with the approved society He would be prepared to investigate inquiries about any referee made without real reason to the regional medical officer

Bellahouston Hospital

Replying to Mr MacLean on November 13th Mr Roberts said the premises and site of Bellahouston Hospital Glasgow were not held on lease but by agreement with the Scottish Red Cross and the Corporation of the City of Glasgow He did not consider that present requirements justified continuance of the hospital beyond January next and had arranged with the committee of Erskine House to increase the number of ex-service patients treated at Erskine House while providing for any out patients at the Ministry clinic in Sauchiehall Street and for cases requiring urgent medical or surgical treatment at the Royal Infirmary These arrangements in no way prejudiced the interests of limbless men or the purpose for which Erskine House was founded They merely extended the constant practice of the last eleven years

International Drug Traffic

Mr Cluses replying to Mr Mander on November 17th said that at the recent preliminary conference of Governments of countries manufacturing drug from opium and coca leaf the Soviet delegation supplied a list of figures for 1927–28 which showed that 76 kilos of heroin 426 of dionine 1,946 of codeine 425 of morphine hydrochloride 24 of pantopon and 447 of cocaine were manufactured In 1928–29 the figures were heroin 31 kilos dionine 234 codeine 1 681 morphine hydrochloride 470 pantopon 145 and cocaine 735 The figures in 1929–30 were heroin 117 kilos dionine 436 codeine 2 854 morphine hydrochloride 632 pantopon 239 and cocaine 1 120 Figures of production of the drugs were not available for Turkey but according to the most recent statistics the annual export of drugs amounted to 5 216 kilos of morphine and 8 652 kilos of diacetyl morphine In India from November 1 to 1924 to October 31st 1925 there were manufactured 140 lb 5 oz. of morphine hydrochloride 2 000 lb of crude morphine hydrochloride 14 lb 11 oz of morphine acetate 2 lb 2 oz. of codeine and 19 lb 15 oz of narcotine From January 1 to December 31st 1926 there were manufactured 224 lb 3 oz of morphine hydrochloride 4 099 lb of crude morphine hydrochloride 4 lb 4 oz of morphine acetate and 23 lb 5 oz of morphine tartrate From January 1 to December 31 1927 the figures were morphine hydrochloride 57 lb crude morphine hydrochloride 281 lb morphine tartrate 8 lb 11 oz and codeine 2 lb 10 oz From January 1st 1928 to December 31st 1928 there was manufactured 159 lb 7 oz of morphine hydrochloride 738 lb of crude morphine hydrochloride 5 lb 6 oz. of codeine and 5 lb of narcotine From January 1st 1929 to December 31 1929 the figures were morphine hydrochloride 119 lb 6 oz. codeine 13 lb 6 oz. and narcotine 10 lb

Cerebro-spinal Fever

Mr Sanders told Lieut.-Colonel Heneage on November 17th that in 1928 in England and Wales there were 9 cases of cerebral *meningitis among troops* with a ratio of 0·11 per 1 000 in Scotland there were 3 cases with a ratio of 0·06 In 1929 in England and Wales there were 25 cases with a ratio of 0·29 and in Scotland 3 cases with a ratio of 0·06 Included in the above figures were 4 cases of cerebro-spinal fever with a ratio of 0·05 in 1928 in England and Wales and in 1929 20 cases with a ratio of 0·23 In Scotland in 1929 there were 2 cases with a ratio of 0·04 Among the civil population in England and Wales 412 cases of cerebro-spinal fever were notified in 1928 with a ratio of 0·01 per 1 000 in 1929 there were 650 cases with a ratio of 0·016 This disease was not notifiable throughout the whole of Scotland but the figures for thirteen of the principal towns of Lanarkshire and Fifeshire showed that in 1928 250 cases were notified being a ratio of 0·10 to 1 000 population In 1929 453 cases were notified with a ratio of 0·17

Poison Gas

Mr Dalton on November 17th told Major Nathan that no representations had been received from foreign Powers about the promotion by His Majesty's Government of experiments in the production and utilization in warfare of poisonous gases and similar noxious substances

Mr MacDonald replying to Mr Wilson on the same day said that the Government had given consideration to the steps which might be necessary for protection of the civilian population in time of war against the use by hostile Powers of asphyxiating poisonous gases No schemes or suggestions had been communicated to the local authorities for the purpose

Mr Sanders on November 17th told Mr Freeman that a comparison of the gross and microscopic appearances of the lungs of men killed by irritant gases in France with those of animals exposed to the same influences showed that the injuries were of similar nature and character Further study of such animal gave evidence of the mode of action of the poison and its effects on vital organs It was thus possible by correlating these experiments with clinical observations on gas patients to formulate curative treatments There was no reason to believe that the connexion between the effects of gas on animal and its effect on human beings which experience in the war established did not continue to hold good

Experiments on Dogs—Sir Robert Gower asked the Prime Minister on November 12th whether he was prepared to grant facilities for the passage during the present session of a bill to make painful experiments on dogs illegal Mr MacDonald replied that in view of the state of public business he could hold out no hope that time would be found for this or similar bill

Instruction on Birth Control—On November 12th Mr Freeman asked whether the attention of the Minister of Health had been called to the recent action of the Warwickshire County Council in authorizing their medical officers to give medical information on birth control to married women Mr Greenwood replied that he had been in communication with the Warwickshire County Council on this matter and had indicated to them the limited extent to which in the view of the Government maternity and child welfare centres might properly be used for this purpose

Milk for School Children—Sir Charles Trevelyan told Mr Alpass on November 13th that in the week ending November 1st 35 600 school children received milk free and 48 600 for payment under arrangement for the provision of meals It was estimated that 500 000 children or about 9 per cent of the elementary school population of England and Wales received a daily supply of milk under schemes organized by the National Milk Publicity Council The corresponding estimate six months ago was 400 000

Imported Cream—Mr Greenwood told General Clifton Brown on November 13th that he would consider his suggestion that imported cream should be subjected to similar examination for tubercle as milk was under the Imported Milk Regulations Most of the cream imported from the Continent was sterilized and the danger of tubercle bacilli in such cream was practically negligible

Muck at Mucking—Mr Greenwood stated answering Mr Oldfield on November 13th that he had been informed by the Hammersmith Borough Council that they had entered into a new contract for the disposal of their refuse at Mucking near Orsett by adequate layering in accordance with any regulations in force relating to the deposit of refuse on the land They were acting within their discretion and as matters stood he had no power to intervene

Preservation of Records of School Children—On November 17th Sir C Trevelyan informed Mr Somerville Hastings that it was left to each local education authority to decide how long they should keep the records of medical inspections of school children He understood however that they were generally kept for about five years after the children had left school

Licences for Experiments on Animals—On November 17th Mr Cluses told Mr Freeman that an applicant for a licence to perform experiments on living animals was interviewed by an inspector who also obtained information from the head of the laboratory where the applicant proposed to work and made any other inquiries that he might consider necessary on the particular case The inspector's inquiries extended both to capacity and to character

Votes in Poor

The number of persons in receipt of poor relief in England and Wales (excluding persons in receipt of domiciliary medical relief only) was 1 107 125 on March 15th and 999 066 on October 25th

Over 51 000 houses were built under the Housing Act 1923 in England and Wales during the year ended September 30th

The Department of Health for Scotland is engaged in an inquiry in the schools of the four large cities in Scotland and of the county of Lanark to ascertain the physical condition of children whose parents have been unemployed for a considerable time

The Services

TERRITORIAL DECORATION

THE King has conferred the *Territorial* Decoration upon the following officers of the Royal Army Medical Corps (T A), under the terms of the Royal Warrant of October 13th, 1920 Major Alexander Leggatt, D S O, Captain John Rowland, *M C*

DEATHS IN THE SERVICES

Colonel Charles MacTaggart, C S I C I E, Bengal Medical Service (ret) died at Campbeltown Argyllshire, on September 18th aged 69 He was born on March 27th 1861, the son of Charles MacTaggart of Campbeltown and was educated at Glasgow University where he graduated M A in 1881 and as M B, C M, with honours, in 1885 Entering the Indian Medical Service as surgeon on April 1st, 1886 he attained the rank of colonel on March 29th 1915 and retired on March 29th 1920 After about three years in military employ he entered civil employment in the jail department in the North West now the United Provinces and served as superintendent of the Central Jails at Benares Agra Allahabad and Lucknow successively In 1902 he was appointed Inspector General of Jails in that province, and held that post until promoted to colonel in 1915 In 1907 he served as a member of the Indian Factory Labour Commission and in 1909 was appointed a member of the Legislative Council of the province On promotion to administrative rank he became Inspector General of Civil Hospitals in the same province and held that post until he retired after five years tour of office He received the C I E on December 11th 1911 and the C S I on June 3rd 1919 He was a keen sportsman both in India and in Scotland and a good shot After his retirement he was made a magistrate for Argyllshire He married Mary daughter of Mr G B M Beatson of Campbeltown

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a congregation held on November 14th the degree of M B, Chir, was conferred on COLLEL Vaughan Bradley

AN ordinary Council meeting was held on November 15th, when the President, Lord Moynihan, was in the chair

A recommendation of the Court of Examiners that the Chesterfield and North Derbyshire Royal Hospital be recognized for the twelve months surgical practice required of non members before admission to the Final Fellowship Examination, was approved and adopted

Mr I I Steward was re elected a member of the Committee of Management

The President reported that the term of office of Mr C H Fagge and Mr Russell J Howard on the Court of Examiners would expire on December 10th next, and that the vacancies thus occasioned would be filled up on December 11th together with the vacancy occasioned by the death of Mr T P Legg

The President reported that in accordance with the application to the Home Office, the research laboratories of the College have now been registered as a place at which experiments on living animals may be performed under the Act 39 and 40 Vic cap 77

The President reported that he had granted the use of the lecture theatre for five lectures on Diseases of bacteria by Mr F W Twort, superintendent of the Brown Animal Sanatory Institution, to be delivered on December 1st, 3rd, 5th, 8th, and 10th at 4 p m each day

The congratulations of the Council were offered to Sir Arthur Keith on his election as Rector of the University of Aberdeen

Dr [illegible] and on November 7th,

Honorary Fellowship

[illegible] was educated at Cooking, *M C* LL D, D Sc, M R C S, [illegible] the University he [illegible] in the University of Toronto, was [illegible] College

Dr Frederick Grant Bair obt[illegible] Professor of Medical Research [illegible] *in Australia* elected an honorary Fellow of the C[illegible] [illegible]ce he [illegible] unto [illegible]ted by the [illegible] and

Primary Fellowship Examination

The following assessors and officers nomina[illegible] pro[illegible]e College of Surgeons of Australasia for the Primary Examination for the Fellowship to be held at Melbourne, Australia, in 1931, were appointed Assessor for Anatomy, Professor F Wood Jones, Assessor for Physiology, Professor W A Osborne, Superintendent of the Examination, Associate Professor Summers, Superintendent of Dissections, W A Bailes The date of the examination was fixed for the last two weeks in August It was reported to the Council that Professor G A Buckmaster and Professor William Wright would accept nomination as the examiners in physiology and anatomy respectively for the Primary Fellowship Examination in Australia next year

Diplomas and Licences

Diplomas of Membership were granted to 149 successful candidates

Diplomas in Public Health and in Gynæcology and Obstetrics were granted jointly with the Royal College of Physicians to 22 candidates and 1 candidate respectively

The names of the successful diplomates were given in the report of the comitia of the Royal College of Physicians printed in our issue of November 8th (p 800)

Licences in Dental Surgery were also granted to 53 candidates

Medical News.

THE Glasgow University Club, London, will dine at the Trocadero, Piccadilly, on Friday, December 12th, at 7 30 p m, with His Grace the Archbishop of Canterbury in the chair Any Glasgow University men who, though not members of the club, desire to be present are requested to communicate with the honorary secretaries, 62, Harley House, N W 1

THE National Association for the Prevention of Tuberculosis has arranged for a series of lectures to be given by Dr Harley Williams next week On Monday, November 24th, a lecture will be delivered at the Village Club, Kingsclere, Hants, at 6 p m, on Tuesday at the Town Hall, Eastleigh, Hants, at 7 30 p m, and on Wednesday at the Town Hall, Lymington, at 8 p m

PARTICULARS of the lectures and demonstrations arranged for next week by the Fellowship of Medicine will be found in our Diary of Post graduate Courses published in the *Supplement* at page 236 Copies of syllabuses and tickets of admission can be obtained from the Fellowship, 1, Wimpole Street, W 1 The list of special courses arranged for 1931 is now available

UNDER the auspices of the Fellowship of Medicine a course in infants' diseases, with special reference to nutritional disorders and dietetics, will be held at the Infants Hospital, Vincent Square, Westminster, from December 1st to 14th The course is specially designed for medical officers of welfare centres and others interested, and will include lectures, demonstrations, and visits to institutions such as St Margaret's Hospital, the United Dairies pasteurizing plant, Willesden, and the venereal diseases centre in Holborn The fee for the course will be three guineas, and further information may be obtained from the secretary of the [illegible], 1, [illegible]o Street, W 1

A POST GRADUATE [illegible]re on cancer will be delivered in the Halifax Infirmary, in connection with the Halifax Division of the British Medical Association, by Professor Beckwith Whitehouse, on November 24th at 3 30 p m His subject will be uterine haemorrhage, with special reference to malignant disease

THE fourth annual congress and [illegible]hibition of the British Institute of Radiology, incorporating the Röntgen Society, will be held at the Central Hall Westmi[illegible] day Many new types of apparatus will be on view, inclu[illegible] the operator's sets, control tables with devices for say[illegible] stands, combined time, Potter Bucky diaphragms, screen[illegible] portable units, x ray and simple type couches, mobile ap[illegible] tubes, and protection devices The[illegible] will be special displays by film manufacturers, and lectures and technical papers will be delivered in the Congress Hall The annual dinner will be held at the Trocadero Restaurant, Piccadilly Circus, W, on Friday, December 5th, at 7 30 p m

THE twenty first annual exhibition of electrical, optical, and other physical apparatus is to be held by the Physical Society and [illegible]ical apparatus is to be held by the Physical at the [illegible] and the Optical Society from January 6th to 8th [illegible] Imperial College of Science and Technology, South Kensington It will include a trade section, comprising exhibits of manufacturing firms, a section for the work of apprentices and learners, for the encouragement of craftsmanship and draughtsmanship in the scientific instrument trade, and a research and experimental section, which will be arranged in three groups (1) exhibits illustrating the results of recent physical research, (2) lecture experiments in physics, and (3) historic physical apparatus The exhibition committee (1, Lowther Gardens, Exhibition Road, London, S W 7) is inviting offers, from research laboratories and institutions and from individual research workers, of exhibits suitable for inclusion in this research and experimental section

THE municipal council of Rheims has opened a subscription for the erection of a memorial to Dr Langlet, who was mayor of the town during its bombardment

THE third International Congress on Radiology will be held in Paris from July 27th to 31st next year The proceedings are to be divided into six sections—namely, radio-physics radiobiology radio-diagnosis radiotherapy medical electrology and natural and artificial sun ray treatment All papers to be presented to the congress, together with a summary of the contents in French, English, and German must be sent by January 1st next to the secretariat of the Congress 34 Boulevard de Vaugirard Paris XV whence full particulars may be obtained An exhibition of radiological apparatus is to be organized in connexion with the congress

THE two hundred and twentieth dinner of the Edinburgh University Club of London was held on November 12th at the Cafe Royal Sir James Barrie was in the chair for the first time since his appointment as Chancellor He spoke of progress of the life of the University The coming of the ladies had changed the undergraduate's life He had been fascinated at the dances which he had attended and a splendour and polish which academic life had not known in his day But the increasing tendency of students to live away from Edinburgh and travel in by motor bus or bicycle caused him anxiety Dr L F Knuthsen proposed the health of the guests and Lord Moynihan expressed the thanks of a distinguished company in an eloquent speech full of humorous insight Lord Aberconway, in proposing the health of the chairman dwelt on the characters in his plays with the zeal of a true admirer The evening was a great success and the speeches brief and memorable Drs Shires and A Landale Clark were responsible for the arrangements

AT the Cheyne Hospital for Children, Chelsea S W 3 a small private ward has now been set aside for children between the ages of 3 and 13 who require prolonged treatment but whose parents are unable to afford the full nursing home fee, yet are able to pay more than the small maintenance charge made in the general wards of the hospital The diseases for which treatment is available in this ward include osteomyelitis anterior poliomyelitis, dislocated hip, surgical tuberculosis, certain forms of infantile paralysis rickets rheumatoid arthritis chorea, and heart disease Minor operation cases, epilepsy mental derangement, infectious cases, and spastic paraplegia are not eligible A weekly charge of 3 to 5 guineas is made by the hospital, and further particulars can be obtained from the secretary

THE Swedish Medical Society has awarded its Pasteur gold medal to Dr Emile Roux, director of the Institut Pasteur of Paris The award is made every ten years

DR. W E MCCULLOCH has conducted an inquiry into the dietaries of the Hausas and Town Fulani of Katsina Town Northern Nigeria his report was published in the *West African Medical Journal* 1929–30 vol iii, together with observations on the effects produced on the national health and some recommendations This report has now been reprinted in pamphlet form by the Government printer, Lagos

DR PERCY J KELLY (Surgeon General) has been appointed an official member of Executive Committee and of the Legislative Council of the Colony of British Guiana

THE Commonwealth Fund of the City of New York a philanthropic foundation existing since 1918 and supported by gifts from the late Mrs S V Harkness has established for British graduate students a number of fellowships tenable for two years in some recognized branch of learning in an American university In 1930 there were 128 entries, and thirty two fellowships were granted—twenty in the faculty of science, and twelve in that of arts The scientific subjects of study included biochemistry zoology, physics sanitary engineering, and organic chemistry Applicants must be unmarried and not more than 30 years old on September 1st of the year of award For the conditions of appointment and the emoluments available application should be made to the secretary of the committee of the Commonwealth Fund Fellowships 35 Portman Square W.1. Applications for fellowships in 1931 must reach the secretary not later than February 9th

ACCORDING to the *Bulletin de l Office International d Hygiene Publique*, 4 618 cases of small pox with 1,699 deaths, occurred in the various French colonies in 1928

MESSRS GEORGE ALLEN and UNWIN Ltd announce for early publication *Dr Barnardo Physician Pioneer, Prophet*, by J Wesley Bready M A , B D , Ph D

A BUST of the well known laryngologist Dr Lermoyez has recently been unveiled in the Hopital St Antoine Paris by Professor Menetrier president of the Académie de Medecine

DR CLAUDIUS REGAUD director of the Institut du Radium, and professor at the Institut Pasteur of Paris has been created Commander of the Legion of Honour

DURING 1926 103 cases of small pox occurred in Paris, with 22 deaths, a mortality of 20 18 per cent and 63 cases in the suburbs, with 17 deaths a mortality of 26.98 per cent. In 1927 62 cases occurred in Paris, with 18 deaths a mortality of 29 03 per cent and 78 cases with 30 deaths in the suburbs, a mortality of 38.48 per cent This outbreak of small pox in a country where vaccination is compulsory is explained by the fact that the law is not strictly observed especially as regards revaccination Moreover the inspection of immigrants especially from North Africa where small pox is rife, is often carried out in too summary a fashion

A MEMORIAL tablet to the late Professor Paul Lecène is to be affixed to the Hôpital St Louis Paris where he was surgeon Subscribers of 100 francs and upwards will receive a medal of Lecene Subscriptions should be sent to M Georges Masson 120, Boulevard St Germain, Paris VI

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR British Medical Journal British Medical Association House, Tavistock Square, W C.1***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager British Medical Association House Tavistock Square W C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 5351 9451 3353* and *9561* (internal exchange four lines)

QUERIES AND ANSWERS

Natural Labour after Caesarean Section

"W M" asks whether anyone knows of a case of a woman who e first baby was delivered by Caesarean section (not performed for contracted pelvis) having had another baby naturally

Analgesia in Midwifery

DR A J HAWES (Wisbech) asks for information as to the methods of anaesthesia and analgesia (if any) commonly used in obstetrics by the midwives of the Scandinavian countries—Denmark Norway and Sweden.

Asthma.

"I T S" writes I should be glad to know if any medical practitioner has had experience of the magnesium hypophosphite treatment for asthma. Are there any contraindications to this treatment and would there be any risk in giving it to a case of bronchial asthma of over twenty years duration? This patient has tried all the usual treatments and has been investigated "from top to toe" but with little or no improvement I should be grateful for details of the method—correct dosage frequency of injections and length of treatment

Inexpensive Dressings.

"CH B" writes A few weeks ago someone inquired about cheap dressings for a poor person with a profusely discharging wound In my judgement no thing can beat sawdust bags made of canvas and stuffed with deal sawdust, as recommended by Mr Cathcart of Edinburgh They can be sterilized in a steriliser or baked at home in an oven

Constipation in a Child

"A M" writes in reply to "A" I would suggest that possibly this is a case for wise and understanding nursery management Is the patient a nervous child or the child of nervous parents or perhaps the charge of an unwise nurse? Perhaps he is ashamed of it or regards himself as a wonderfully interesting case Perhaps he is given quantities of sloppy food If he had a direct incentive to do as others do such as making his a condition of remaining at a well liked boarding school or could be persuaded to get his mind right off it he would no doubt succeed Perhaps the child feels hopeless about it or may be

in dread of punishment or disgrace Nervous children will often entirely conceal such feelings Personally I should not give any of the drugs mentioned I find isacon suitable for children, and they like the small size of the tablets One may be taken each night

'J R D' writes My eldest son, now aged 10, began to have fairly severe constipation at the age of 1½ to 2 years, he passed enormous hard stools if the bowels had not been open for a day or two, and even with daily motions the stools were very large, and it was difficult to correct this condition Great care has been taken to go to stool at fixed hours, but paraffin and sometimes also syrup of figs have had to be continued daily When 1 to 2 years old he passed several times a more or less complete bowel cast He still takes about three drachms of paraffin daily, and passes one stool each day, not nearly so large in comparison as formerly About once a week there is no evacuation, and then the laxative syrup is given in addition The only real point of interest is that he is slowly *growing out of it*" He is active and *on the highly strung side* He was a nervous infant, awakening at a sound, and some years ago was for a long period subject to acidosis attacks These are now prevented by alkaline draughts, given at the first warning My other boy is quite normal in disposition and habits

Cyanosis with Collapse

DR T H WIGNALL (*Manchester*), *replying to the inquiry of* Dr L R Lemprière on November 15th (p 848) about his case of cyanosis with collapse, writes In my capacity of works surgeon to the British Dyestuffs Blackley, I have seen many cases of acute aniline poisoning, and the case so clearly described by Dr Lemprière strongly suggests acute anilism The boy was treated quite properly for the condition and recovered, as these cases, when not too severe, do I think arsenic cannot be blamed In any future case I should advise examination of blood for methaemoglobin, and, as a preventive precaution, I should advise boys not to get paint colours in the mouth or on the hands I do not think any medicinal form of aniline derivatives had been taken in this case Acetanilide has produced similar results in susceptible persons, and recovery without detriment usually occurs

"R C writes In reply to Dr L R Lemprière's inquiry The case seems to be one of methaemoglobinaemia (or sulpho haemoglobinaemia) Vide Saville's *System of Clinical Medicine*, fifth edition, p 38

Income Tax

Assessment of Nursing Home

"X X has been in surgical practice for some years, and in April 1929, commenced a surgical home as an adjunct to his practice The consulting room and *x* ray room are on the same premises The inspector of taxes claims to treat the home as a separate matter, which will adversely affect his income tax liability, and an appeal to the Commissioners has been lodged

*** The matter is not free from doubt, and a decision will to some extent turn on the precise facts of the case, but on the whole we think that the inspector has the stronger legal position The home is in the nature of a business run in connexion with a practice, and some of the distinguishing marks of a profession are not present in the ownership and management of a 'home' The two do not necessarily constitute a single unit of assessment because they are under the same control and ownership, and carried on in the same premises The profits of a business are assessable under a different case" of Schedule D from those of a profession, and on the facts the "home' may properly be held to be a 'business' managed and owned by a professional man

Cash Basis

"TAY bought a practice as from August 1st, 1929, and is, of course, assessable in respect of the year 1929-30 on the amount of the profits of the practice for the period from August 1st, 1929, to April 5th, 1930 Can he claim to calculate his gross income at the amount of his cash receipts?

*** No, the correct basis is the amount of the cash receipts plus the amount of the outstanding debts as at April 5th, 1930, but after taking off that sum a carefully estimated allowance for bad debts It will be realized that in such circumstances the adoption of the cash basis would mean deducting eight months' expenses from the equivalent of five or six months' gross income The cash basis is legitimate only when the cash receipts for the earlier years fairly counterbalance that part of the year's bookings which are uncollected at the end of the year

Radium Needles Allowance for Exhaustion

"Y Z's firm has about £1,000 worth of radium in needles, and has claimed 25 per cent wear and tear allowance for income tax purposes on the ground that as used the life of the needles is not more than four years The inspector of taxes declines to allow depreciation, and points out that replacement expenditure can be allowed when the needles are renewed

*** The inspector is probably correct in refusing the depreciation allowance, because that is applicable only to "plant and machinery a phrase that implies something substantial, and having moving parts suffering wear and tear by friction, etc. The replacement allowance applies to loose tools, implements, etc, and, on the whole, does seem to cover such apparatus as radium needles rather more appropriately *But the* result of waiting for the allowance of replacement expenditure—if and when the needles are renewed—imposes a clear hardship, and 'Y Z' is justified in not yielding up his contention without a struggle An alternative contention which appeals to us as more capable of sound argument would be somewhat as follows Both the provisions so far discussed relate to assets which in themselves are permanent, but which suffer wear and tear in use, and the distinction does not work unfairly provided that the 'tools' are individually comparatively inexpensive, which is normally the case Radium needles, however, are different in their nature, in that they have in any case a limited effective life In this they are analogous to 'consumable stores —such as stocks of material, coal, contractors' equipment, etc—the practice with regard to which is to estimate the amount consumed for each respective contract or over the year's working On that line of approach an allowance might be claimed, not as 'wear and tear,' but as the amount 'consumed" it being understood that when renewal does take place an allowance *shall be given of the replacement cost, less the* sums allowed in respect of past 'consumption

LETTERS, NOTES, ETC

Diet and Efficiency of Field Labourers

IN an article reprinted from *Tropical Agriculture* (vol vii, No 2, p 40) Dr E A Seagar, professor of hygiene and sanitation, Imperial College of Tropical Agriculture, gives a preliminary account of an investigation into various influences adversely affecting the efficiency of agricultural labourers in Trinidad, with especial reference to diet, health, fatigue, and psychological factors The inquiry began a few years ago, and included a systematic collection of dietetic and medical records of about 800 East and West Indian labourers on sugar and cacao estates, which was undertaken partly to establish a correlation between diet and disease Among the general results of the survey the dietary of the East Indian labourer appears to be superior in some respects to that of the West Indian, especially in sugar plantations, where the dietary statistics are stated to be consistently better In both groups, however, the staple articles of diet—namely rice, white flour, salt fish, and Irish potatoes—were found to be deficient in fats, proteins, and vitamins The native workers apparently prefer to buy imported and tinned foods rather than cultivate more nutritious products at home Health statistics revealed that a large number of labourers had marked cardiovascular degeneration, which reached an acute stage by the age of 40 This condition is thought to be definitely related to faulty diet and excessive consumption of tobacco and spirits. Some evidence was also obtained that deficiency of vitamin A was chiefly responsible for bronchial asthma and for some of the conjunctival affections among the East Indians The percentage incidences of various diseases, such as ankylostomiasis, malaria, and syphilis, are represented diagrammatically, but the value of the figures is limited by the fact that they were based only on obvious clinical manifestations While the investigators recognize that physical and climatic conditions may lower resistance and indirectly weaken the will to work, they consider that much could be done by instruction in healthy habits of living and by the general adoption of a suitable dietary A more tentative suggestion is the gradual introduction of educational measures to change the attitude of the field labourer towards his methods and hours of work, which amount, on an average, to about twenty hours a week As this question, however involves deeply rooted family and racial traditions, it is doubtful if such habits and customs would be readily abandoned, even if they were, the psychological effect in other directions seems at present incalculable

Varicella and Herpes

"K B C" writes On October 25th I vaccinated a young lady aged 19 On the 26th she developed a typical chicken pox rash, which ran a normal course On November 9th I saw her mother, aged 38, with mild chicken pox, on the 10th her stepfather, aged 39, had developed chicken pox which he has had very severely, running a temperature of 103° F for several days He had also two well marked patches of herpes, one over a right intercostal nerve and one over the course of the left external cutaneous nerve As his illness was severe, the diagnosis was confirmed by the medical officer of health

Vacancies

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 48, 49, 50, 51, 55, and 56 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52, 53, and 54

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 235

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine

457 Paroxysmal Hypertension of Nervous Origin

VARIOUS authorities have stated that arterial hypertension may be due to irritation of the fine terminal branches of the originating plexus of the pneumogastric or of its trunk. F. TREMOLIÈRES, J. LHERMITTE, and P. VÉRAN (*Rev. de Med.* October, 1930, p. 657) fully report a case, followed from its onset to necropsy, which proves that it may also be caused by irritation of the trigeminal. A man aged 28, who had no pathological or syphilitic antecedents, was first attacked by a right frontal zoster-like eruption with slight fever. Three days later a hypertensive crisis with convulsive coma, hyperazotaemia, and albuminuria supervened. These symptoms disappeared in forty-eight hours. At varying intervals during a year four similar attacks of progressively increasing severity occurred. After the third one, definite signs of permanent hypertension, chronic nephritis, and myocardial failing were noted. The patient died two days after the last of these attacks. The post-mortem examination revealed intense, very peculiar lesions (cystic dilatation) of both Gasserian ganglia, considerable hypertrophy of the left ventricular wall, and two small, contracted sclerotic kidneys. From a study of the literature the authors conclude that the patient suffered from a double paroxysmal hypertension, both vascular and of the cerebro-spinal fluid. They believe that the Gasserian inflammatory lesions and the dermatitis were caused by an infecting microbe, and that the dermatitis could only be classed among the zoster-like eruptions and not as a true herpes or zona. Both clinically and anatomically three clinical elements predominated: the recurring facial dermatitis, the vascular and cardiac troubles, and the nephritis, there were three corresponding anatomical elements: the Gasserian ganglionic lesions, the myocardial hypertrophy, and the renal sclerosis. These were chronologically related, and two chief points are emphasized: the priority of the eruption and hypertensive crises and their clear linking and the subsequent development of the chronic nephritis with the simultaneous appearance of permanent hypertension. Since the first renal troubles became manifest eight months after the first hypertensive attack they appear to be the result rather than the cause of the hypertension. The renal lesions were probably due to two causes: the mechanical action of the hypertensive waves and the infection. The hypertensive crises were probably due to the excitation produced by the Gasserian inflammation which, passing by the ascending and descending roots of the trigeminal nerves to the hypothalamic vaso-constrictor centres, caused the attack by a violent vaso-constriction. Besides the symptoms enumerated the patient showed a marked uric acid increase in the blood and the urine, a decided hypercholesterolaemia, and a moderate hyperglycaemia.

458. Sclerosis and Occlusion of the Coronary Arteries.

As the result of a post-mortem study of 44 cases of coronary disease, 26 presenting sufficiently advanced lesions of sclerosis to be termed coronary stenosis and 18 a thrombus in a coronary artery, O. KLOTZ and W. LLOYD (*Canadian Med. Assoc. Journ.* September, 1930, p. 359) arrived at the following conclusions. Cardiac coronary disease usually affects male adults between the ages of 55 and 60 (rarely before 30); it is the outcome of endarteritis associated with atheroma and calcification. The arterio-sclerotic process causes stenosis of the vessel, but complete occlusion results from thrombosis. In no case had thrombosis developed without sclerosis; sclerotic patches in the arteries were multiple, various branches of the right and left coronary being simultaneously involved. A stenosing endarteritis in both coronary arteries intensifies the myocardial damage which results from nutritional disturbances; unilateral coronary affection may progress markedly without causing myocardial injury or cardiac manifestations. If the stenosis progresses slowly the anastomotic circulation between the two coronaries compensates for the vascular derangement when one coronary alone is seriously affected. Rapidly occluding processes as found in thrombosis induce more serious myocardial disturbances than the slowly progressive and compensating stenoses associated with chronic endarteritis. The stenosing arteriosclerosis appears to originate in a primary endarteritis or in an intimal degeneration followed by endarteritis. A direct relation between rheumatic lesions of the arteries and the sclerosis, or between syphilis and the stenosis, was not demonstrable. The manner of distribution of the sclerosis does not support the contention that the arterial lesions result from mechanical stresses due to unique branching of the coronary arterial system. The causative factors of endarteritis and atheroma of the coronary arteries are still undetermined.

459 DISCUSSING various points in coronary thrombosis R. W. SCOTT (*ibid.*, p. 366) states that this condition has as an anatomical basis coronary arterio-sclerosis. The usual case of coronary thrombosis presents fairly typical symptoms, and a correct diagnosis is easy. In doubtful cases particular attention must be paid to the cardiovascular system. A history of hypertension, breathlessness on exertion, tightness in the chest, anginal pain, and indigestion should be carefully scrutinized. Distant heart sounds, a gallop rhythm, pulsus alternans, cardiac disturbances such as extrasystoles, auricular fibrillation, low blood pressure, and feeble precordial impulse are important objective findings. A pericardial friction is indicative of myocardial infarction from coronary thrombosis. In difficult cases electrocardiograms afford valuable information. Characteristic distortions of the ventricular complexes are known to result from infarction of the cardiac wall.

460 Medical Shock.

D. A. ATCHLEY (*Journ. Amer. Med. Assoc.*, August 9th, 1930, p. 385) emphasizes the importance of shock as a fairly frequent serious complication in certain medical conditions. Characterized by vasomotor collapse, fall in blood pressure, and consequent failure of the circulation, it is often confused with other fatal causes such as cardiac or respiratory failure, but is more capable of successful treatment. Whatever the cause may be, a disproportion exists between the blood volume and the vascular bed, the former being decreased through haemorrhage or loss of fluid and the latter increased from capillary dilatation. Two types occur—namely, an hydraemic shock from simple loss of blood volume as in diabetic coma, and toxaemic shock, dependent upon capillary paralysis from some bacterial or protein substance such as occurs in the vasomotor collapse in pneumonia. Treatment is more or less independent of the cause. It aims at rapidly increasing the blood volume by (1) intravenous administration of 50 c.cm. of a 50 per cent. solution of dextrose which draws fluid from the blood stream into the tissues and is more successful in toxic than in anhydraemic shock, (2) intravenous injections of from 500 to 1,000 c.cm. of salt solution, and (3) blood transfusion if necessary. Since the third procedure may turn the scale when the first two have failed every patient likely to develop shock should have his blood grouped early in the illness. Vasoconstrictors such as adrenaline are contraindicated; they are dangerous because they affect blood vessels already constricted to the disadvantage of the capillary circulation. The intravenous route of injection should always be preferred to the subcutaneous or intramuscular owing to the greater rapidity in response; it is important to keep the patient as warm as possible.

Surgery.

461 Tumours of the Cauda Equina.

TUMOURS of the cauda equina present a very special clinical picture depending on their site, duration, size, and association with osseous lesions and often on the inevitably tardy diagnosis. ANDRÉ THOMAS, FERRAND, SCHAEFFER, and DE MARTEL (*Paris Méd.*, October 4th, 1930, p. 292) report a case characterized by another marked symptom—namely, meningeal haemorrhage. A man, aged 33, had had for twelve years attacks of pain in the pelvis, buttocks, and thighs at first intermittent, these became more frequent. For three years sphincter troubles with vesical infection had been present, and for a year he had had permanent spinal rigidity. The pains, most intense in the regions mentioned, radiated along the whole dorsal spine and into the shoulders. The spinal rigidity amounted to an actual opisthotonos with a specially marked curvature in the dorso-lumbar region. It was evidently related to the haemorrhage, since it ceased with the resorption of the blood. The authors consider that this indicates that the rigidity was probably a reflex contracture caused by irritation of the nerve roots by the blood. The most striking characters of the haemorrhage were its persistence and abundance, for eight days the spinal fluid

was almost entirely composed of pure blood Other striking symptoms were abolition of both Achillis reflexes, absence of fever, and a lifelong sexual frigidity The intense spinal rigidity and predominance of the haemorrhage in the lumbar cul de sac suggested that the blood leakage was of low origin, the anaesthesia of the thighs, buttocks, and perineal region, the abolition of the Achillis reflexes, and the sphincter troubles, indicated compression of the sacral roots The authors believe that all the symptoms could be attributed to the growth The tumour was localized by multiple spinal punctures and lipiodol injection, this method is commended by them for localizing tumours in this region Under general ether anaesthesia, laminectomy was performed, and the neoplasm, the size of a large olive, was removed, three spinal roots were intimately adherent to it being first divided The tumour proved to be a benign, very vascular neuroglioma The patient markedly improved after the operation, though an incomplete paralysis of the extensors of the right foot resulted from the division of the spinal roots In view of the high mortality (over 50 per cent) attending these tumours, this is considered a successful result

462 Operative Measures in Lumbo sacral and Sacro-iliac Affections

SINCE their inception W C CAMPBELL (*Surg, Gynecol and Obstet*, September, 1930, p 381) has employed fusion operations in cases with affections of the lumbo sacral and sacro iliac articulations, and mentions the indications for their use Pain low down in the back may be due to various causes, these may be divided into those in which the site of the disease is in the spine and pelvic articulations, and those in which the pain is referred from organs not connected with the spine Only the first group is dealt with in this paper The causative agents which involve the articulations are infection, trauma, postural defects, and congenital anomalies When possible the exact site of the lesion must be determined, it may be in the articular process of the lumbo sacral region, the intervertebral disc, the intervertebral foramina, or in the sacro iliac articulations This can usually be accomplished by a systematic and careful physical examination, which should be made with the patient successively in three positions—standing, sitting, and lying Diagnostic points in this examination are enumerated Radiograms are by no means conclusive, however, differentiation can usually be made by a physical and radiological examination The object of operative procedures in these affections is to fix or splint, by an internal osseous bridge, the affected area, which may be one, two, or all three articulations The methods employed by Campbell have been those of Albee and Hibbs, of Smith Petersen, and one devised by himself, which is described The present author emphasizes the point that conservative measures, when possible, should be employed before fusion operations are considered These operations are indicated in all cases with tuberculous involvement, and they are advisable in cases with persistent symptoms and definite abnormalities as demonstrated radiologically If the symptoms persist and no *x* ray proof of a lesion is obtainable an operation is indicated only when all extraneous causes have been carefully excluded Fusion of the lumbo sacral articulation causes no practical disability, though flexion of the spine may be slightly limited Fusion of the sacro iliac joints gives rise to no disability These procedures should be carried out with precision in order to avoid shock, not more than one hour should be taken for the operation The mortality from fusion of any one articulation is practically nil, and, with sufficient care, should be exceedingly low in all the other operations The excellent results obtained in 63 cases (50 non tuberculous and 13 tuberculous) are indicated in tables

463 Hunner Ulcer of the Bladder

C C HIGGINS (*Urol and Cut Rev*, October, 1930, p 665) records 38 cases of Hunner ulcer, or "elusive ulcer" of the bladder, which was first described by Nitze in 1906, and later by Hunner of Baltimore in 1914 In 29 of the 38 cases the patients were women, and 25 were first noted in middle life, the youngest patient being 26 and the oldest 69 The characteristic symptoms are frequency of micturition both day and night, and usually dysuria and suprapubic pain, they are typically chronic, though remissions may occur Haematuria was present in 6 cases, but is not a characteristic symptom The diagnosis is established by cystoscopic examination, which shows a sharp line of demarcation between the normal bladder mucosa and the inflamed oedematous area, in the centre of this area there are one or more minute red ulcers, on the periphery of which a network of radiating arterioles may be seen Usually the ulcers are small and may be multiple, sometimes they are covered by a small amount of fibrin but they never have a sloughing base as in tuberculosis One of the most important phases of the treatment consists in eradication of foci of infection in the teeth, tonsils, sinuses, or kidneys Fulguration under sacral anaesthesia should be applied intensely over the ulcer, and less intensely to the surrounding area If fulguration is unsuccessful, resection should be performed

464 Treatment of Otorrhoea

R MENNITI IPPOLITO (*Arch Ital di Otol, Rinol e Laringol*, August, 1930, p 386), who records eleven illustrative cases in children aged from 5 to 12, states that in subjects of adenoids many forms of acute and chronic suppurative otitis media can be cured in a relatively short time by removal of the hypertrophic pharyngeal tonsil and infected muco-pus In dealing with cases in which the causation of the otorrhoea is not obvious it is, therefore, a good rule to examine for the presence or previous existence of adenoids. In some cases the operation may not have been a radical one, or post operative cicatrices may have been left round the openings of the Eustachian tubes The good results as regards hearing obtained from the operation are partly due to the improved ventilation and circulation in the middle ear and its adnexa, and partly to facilitation of drainage and destruction of the area of infection It is important that the operation should be performed before mouth breathing has become a habit and the suppurative process in the ear is too advanced, since the less progress the disease has made, and the earlier the operation is performed, the more brilliant the results are likely to be

Therapeutics.

465 Dextrose in Poisoning by Barbital

WHILE working on hyperglycaemia, C A JOHNSON, A B LUCKHARDT, and J A LIGHTHILL (*Journ Amer Med Assoc*, August 23rd, 1930, p 576) noted the apparent rapid recovery of barbitalized dogs when treated with large doses of dextrose solution This led to the use of diuretic measures in one clinical case of attempted suicide with barbital, and to certain experimental work which is now reported In these tests it was found that in dogs receiving 1 litre of 10 per cent dextrose solution the recovery time was reduced in most cases to less than one half The average time required for recovery in the case of dogs receiving barbital alone was between 36 and 39 hours, while in the case of dogs receiving similar doses of barbital followed by dextrose the interval ranged from 14 to 18 hours Gower and Tatum have suggested that, on the basis of the excretion of barbital in the urine, the most rational treatment of acute barbital poisoning is to maintain optimum renal function The above experiments confirm this, and the present authors consider that this method of hastening the recovery time is useful in cases of anaesthesia and poisoning with barbital and other barbituric acid compounds

466 Combined Administration of Arsenic and Gold in Tuberculosis

G F CAPUANI (*Paris Méd*, August 30th, 1930, p 176) recalls the early anxiety of Moelgaard as to the possibility of there being some incompatibility or even antagonism between sanocrysin and other therapeutic substances, particularly because research revealed the occurrence of a very toxic reaction when animals were treated simultaneously with sanocrysin and arsenic anhydride Capuani, however, having treated a patient with sanocrysin and sodium cacodylate with very satisfactory results, repeated this joint administration in 22 other cases without unpleasant sequels In fact, the progress of the patients was similar to that of those treated by sanocrysin alone, except that there seemed to be less loss of weight when the two drugs were thus associated Cases of syphilis and tuberculosis have also been treated simultaneously with arsenobenzol and gold, and also with neocrysol—a compound in which a molecule of arsenic in arsenobenzol has been replaced by gold, no toxic results have been recorded, this is not considered surprising in the latter case, for the gold content is only 4 per cent Capuani has made experiments *in vitro* with sanocrysin on the one hand, and sodium cacodylate, arrhenal, the arsenobenzols, and arsenic anhydride on the other, in the last case reduction of the sanocrysin was observed He discusses the biochemical storage of arsenic in the tissues, and concludes that arsenic anhydride, given after or during treatment with sodium aurothiosulphate, exerts an increased toxicity This effect is not due to chemical reaction between the two substances, but to the fact that the reticulo endothelial system, paralysed by the gold, cannot fix the arsenic and so protect the body against this poison In the case of other arsenical preparations this danger does not exist because they are less toxic, and the defensive role of the reticulo endothelial system is of little importance

467 Digitalis in Lobar Pneumonia

W L Mills and L Wilcox (*Amer Journ Med Sci* September, 1930 p 348) record the results of an investigation carried out continuously during 1928 and 1929 by a committee of the physicians of the Bellevue Hospital New York, into the effects of digitalis in pneumonia. Patients were considered in four groups—namely, those receiving neither serum nor digitalis those who received serum only, those who received digitalis only, and those who received both serum and digitalis The drug was administered rapidly, but in divided dosage to prevent toxic effects During the first year the maximum digitalizing dose never exceeded 0 15 of a cat unit per pound of body weight, this was divided into six hourly doses The administration was stopped if any toxic symptoms occurred such as vomiting or heart block and because of their too frequent incidence the dosage was halved during the second year It was found that for every 100 fatal cases in the control there were 122 deaths in the digitalis treated group, and that in all types except Type II the mortality of the digitalis treated cases was higher than that of their controls In the most severe cases with positive blood cultures the mortality rates in the control and the digitalis treated groups were the same, while in the milder cases with negative blood cultures, the mortality was 14.3 per cent higher for the treated group The committee was unanimous in its opinion that the results of the investigation contraindicate the administration of digitalis in lobar pneumonia, though it suggested that the study of a larger number of cases over a series of years would be valuable

Anaesthetics

468 Spinocain Anaesthesia.

It was noted in the Cleveland Clinic, where spinocain is exclusively used for spinal anaesthesia, that complete anaesthesia was not obtained in about one tenth of the cases, and T E Jones (*Med Journ and Record* September 3rd, 1930, p 226) states that for this reason the original Pitkin method was modified Using this technique many cases developed complete motor paralysis of the extremities with incomplete anaesthesia, and it was thought that this might be due to an insufficient amount of the solution reaching the sensory (posterior) roots Therefore the patient is now turned on his face instead of his back immediately after the injection, and is left there until tests indicate that the anaesthesia has reached the required level For the injection, the spinal canal is entered between the third and fourth interspace While the solution is being injected the patient usually lies on the side opposite to that in which the incision is to be made In cases of middle incisions he may lie on either side After the operation the foot of the bed is raised so that the head is about 10 degrees lower than the feet Before the injection of the spinocain, 1 grain of ephedrine is given and it is repeated if necessary during or after the operation Adrenaline in a dosage of 4 or 5 drops though more transient in its action, is more effective after the introduction of this anaesthetic Spinocain causes slightly less nausea than other solutions The administration of oxygen during the operation often tends to alleviate the nausea and vomiting Inhalation of aromatic spirits of ammonia is also helpful No deaths attributable to the anaesthesia have occurred and the only complication noted (in only three or four cases) has been persistent headache lasting from seven to ten days For all rectal and perineal operations, 1 c cm of spinocain mixed with approximately 2 c cm of spinal fluid is used For pelvic operations, or any below the umbilicus 2 c cm of the solution is required, and for operations below the diaphragm 3 c.cm Spinal anaesthesia has not been attempted in operations above the diaphragm

469 Ethylene Anaesthesia.

J T Nix (*Anesthesia and Analgesia*, July–August 1930 p 171) discusses the present status of ethylene anaesthesia from an experience of 12,000 administrations during the past six years In the obstetrical department of a hospital in New Orleans, with an average of 700 deliveries annually, ethylene has almost entirely displaced chloroform and ether it is being used for all normal cases and for most complications Nix has used it in over 2,500 surgical cases and 250 obstetrical cases and considers the contraindications for its use are fewer than in the case of ether Such contraindications are (1) arterial hypertension and nephritis, since acute nephritis and albuminuria have followed its use in patients with existing kidney irritation or hypertension (2) pulmonary irritation or infection because of the risk of aggravating the condition although no other general anaesthetic would be better in this respect (3) brain cases (4) the presence of a flame cautery, or spark, and (5) a low atmospheric humidity at or below 50 since explosions from static electricity do not occur if the humidity is above 55 The author concludes that ethylene and oxygen without ether is the anaesthetic of choice for almost the entire field of general surgery and obstetrics, in the event of ether becoming necessary during an operation only a minimal quantity is required While chest colds acute bronchitis and pulmonary tuberculosis are unfavourably influenced by its use the "head cold" is improved Nix adds that with complete co-operation between the surgeon and an anaesthetist experienced in its administration ethylene approaches nearest to the ideal of a general anaesthetic for use in southern climates

470 Sodium Amytal-Nitrous Oxide Anaesthesia for Thyroidectomy

F B Ramsey and W D Little (*Surg, Gynecol and Obstet.*, September 1930, p 352) enumerate certain advantages resulting from the combined use of sodium amytal and nitrous oxide as an anaesthetic in thyroid surgery, the reactions during and after its administration in 27 consecutive thyroid ectomies are recorded Comparatively small doses of sodium amytal induced a light sleep which was sufficient for preparation and preliminary measures During the actual operation nitrous oxide gas with an unusually high percentage of oxygen was given This combination makes an ideal anaesthetic when the operation does not require marked muscular relaxation, such as operations on the thyroid and on the chest The cyanosis which so often accompanies nitrous oxide anaesthesia annesthetic depression, and irritation of the respiratory tract did not occur There was freedom from nausea and vomiting, and no signs appeared of post operative mania or excitement Prolonged sleep did not follow The post operative course in general was good, the only complication being auricular fibrillation which occurred in five cases and was satisfactorily controlled with digitalis The sodium salt was administered intravenously in 23 of the cases and by rectum in the 4 others Owing to its greater possibility of control the intravenous method is considered preferable The intravenous dose varied from 12 to 20 mg per kilo of body weight the majority received approximately 15 mg per kilo (1 grain per 10 lb body weight) Considerable latitude in dosage was found necessary in view of individual reactions When given by the rectum the dosage employed was 20 to 30 mg per kilo In addition each patient received a pre operative dose of morphine (1/6 to 1/4 grain) this was combined with atropine (1/150 grain) in eight cases Low percentages (75 to 85 and in some cases 65 to 75 per cent) of nitrous oxide produced satisfactory anaesthesia by this method W Bourne, M Bruger and N B Dreyer (ibid p 356) consider that with the increasing use of sodium amytal greater knowledge of its pharmacological actions is desirable Accordingly they performed a series of experiments relating to its action on various functions of the body The results showed that the drug has very little action on liver function thus comparing favourably with ether It also depresses urine formation much less than ether The combined carbon dioxide and hydrogen ion concentration of the blood are increased the former change being possibly due to the depressed respiration and the latter to disturbed phosphoric lactic acid metabolism Hydraemia and a fall of body temperature also occur

Obstetrics and Gynaecology

471 Treatment of Abortion.

Cpann Petersen (*Ugeskrift for Laeger*, September 4th 1930 p 837) discusses the comparative merits of radical and conservative treatment of abortions in the light of a statistical analysis of material collected in a Danish communal hospital In the period 1914 to 1928 inclusive 1 148 cases of abortion—threatened, complete or incomplete—from the first to the sixth month of pregnancy inclusive were admitted to hospital Approximately 85 per cent (930 out of 1 099) of the patients were in the second or third month of pregnancy whereas only 15 were in the first month As many as 1 118 were given radical treatment most of them (1 016) receiving it on the first or second day of admission while the remaining 102 underwent radical treatment after expectant measures had been continued for two days or longer In 28 cases the treatment was conservative In nearly all the cases receiving radical treatment the abortion was incomplete Among the 1 148 cases there were 7 deaths a mortality of 0 61 per cent there were no deaths among the 755 women who were afebrile on admission The 7 deaths occurred among the 931 cases which were febrile on admission (over 100 5°) or became so before active treatment was instituted the mortality in this class was therefore 1 79 per cent After reproducing various tables, and comparing his own findings with those of others,

Graan Petersen comes to the conclusion that active treatment is superior to the conservative in arresting haemorrhage and in reducing the average duration of fever and of the stay in hospital He favours early evacuation of the uterus instead of waiting a few days, for the percentage of febrile cases was higher among those in which evacuation was deferred than in those when evacuation was prescribed at once He recommends early evacuation (within the first two days of admission to hospital) for both febrile and afebrile cases, since he finds this course the most satisfactory both in relation to haemorrhage and to infection He insists, however, that every case must be judged on its merits

Sarcoma of the Cervix.

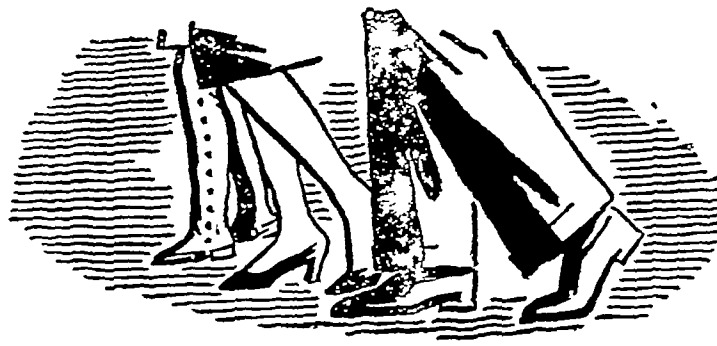
L E PHANEUF (*Surg., Gynecol and Obstet.*, October, 1930, p 500) adopts Piqnand's classification of cervical sarcomata into two groups the racemose, which macroscopically resembles a bunch of grapes, and an ill defined group comprising all other varieties Racemose sarcomata increase rapidly in size and soon fill the vagina, which may become greatly distended, they may even herniate outside the vulva Abundant discharge, often fetid, is present, though the neoplasm does not greatly tend to ulcerate The second group may be subdivided into two large classes sarcomata of the mucosa and of the parenchyma The former are much commoner, and may be diffuse or circumscribed The diffuse form is very rare, it presents an ill defined infiltration with thickening and vegetation of the mucosa, which is wholly or partly involved The tumour rarely invades the uterine body, but extends outward to the vagina In the beginning it is limited to the mucosa, but later the muscular tissue is involved The most frequent of all cervical sarcomata is the circumscribed, which may be sessile or pedunculated The sessile form exactly resembles a papillary epithelioma, differing from it only in its soft consistency, greater size, and its tendency to gangrene and suppuration The pedunculated sarcoma or sarcomatous polyp is of variable size (rarely larger than an orange), and is attached by a pedicle, which is generally implanted in the canal, not usually on the external vaginal surface Parenchymatous sarcoma is rare, and usually takes the polypous form Primary neoplasms of this type are almost always due to sarcomatous degeneration of a fibrous polyp The tumour is rather regular in shape, smooth or bossed, its consistency, variable at different points, is firm Round cell, spindle cell, and ramified cell sarcomata are found Cervical sarcomata always begin insidiously, and may evolve for a long period without any functional symptom As in carcinoma, the chief symptoms are haemorrhage, pain, and serous discharge The average duration of life appears to be from eighteen to twenty four months. Metastases occur in the parametria, vagina, peritoneum, lungs, and the bony and central nervous system Treatment should be radical—abdominal hysterectomy according to the Wertheim technique A case is reported which presents many interesting points The disease was evidently in an advanced stage, though no post operative local recurrence could be found, the patient died of what appeared to be a cerebral metastasis at the end of five months Most cases reviewed in the literature terminated fatally from metastases Possibly earlier recognition of the disease might be followed by better results

473 Treatment of Tuberculous Pyosalpinx

H VIOLET (*La Gynécol.*, August, 1930, p 467) describes a course of treatment which he has found valuable in cases where a radical operation on tuberculous pyosalpinx would endanger the life of the patient Through observing the progress of a woman who had a tuberculous pelvic abscess which had opened spontaneously, the author was led to try the treatment which he has since found successful Following the spontaneous opening no surgical treatment was possible, but a course of radiotherapy succeeded beyond expectations Violet quotes a case in which a large pelvic abscess was relieved by colpotomy The immediate result was good, and there followed a course of ultra violet rays which improved the general condition though the vaginal suppuration continued Complete extirpation was out of the question Eight deep x ray applications were given, after one month there was marked diminution of the discharge, and the adnexal mass was reduced to the size of a nut The author has used a similar method of treatment in 100 cases, and finds the results better than those produced in any other way The contraindications to complete removal are, according to Violet, incomplete localization, invasion of the pelvic cellular tissue, and invasion of the intestine Deep penetrating rays are used, similar to those employed for uterine cancer, one application a week is given until a total of eight is reached

Pathology.

474 The Cerebro-spinal Fluid in Late Syphilis



A WITTGENSTLIN (*Deut med Woch.*, August 29th, 1930, p 1474) has investigated the serum reactions and the cerebro spinal fluid of 128 syphilitic patients and observed them over a course of five to ten years All the patients were in a late stage of the disease, but without clinical signs or symptoms at the time of the initial examination In 42 patients the the serum and spinal fluid were both negative, and although in three cases an apoplexy ensued, which may have been related to their syphilitic infection, true neurosyphilis never developed, 30 other patients had negative serums, with pathological spinal fluids, and of these no fewer than 26 showed signs of neurosyphilis Of the sero positive cases, in 15 out of 21 with a pathological fluid, and 2 out of 35 with a normal fluid, neurosyphilis supervened The author concludes that it is thus clear that while the serum reactions afford no guidance in prognosis, the examination of the cerebro spinal fluid is of the greatest importance When repeated lumbar punctures were made it was found exceedingly rare for a normal fluid to become pathological in this stage of the disease, or for a pathological fluid to become normal without treatment As regards latent or developed neurosyphilis, the author finds that a combination of ordinary specific therapy, intrathecal salvarsan, and non specific (for example, malarial) therapy is the most effective If the cerebro-spinal fluid can be made normal by these means, the prognosis appears to be as good as in those cases where the fluid was normal on first examination.

475 Intestinal Bacteria in the Breast-fed Infant.

E STRANSKY and A WASITZKY (*Monats f Kinderheilk.*, August, 1930, p 517), as the result of their investigations, came to the following conclusions The bifidus acidophilus flora of the breast fed infant should be attributed to the abundance of carbohydrates and scarcity of albumin The only ferments detected in the killed organisms were amylase and rennin, proteolytic ferments were entirely absent. It is probable that the bacteria develop their activity in the lower part of the small intestine, where sugar is still present In the large intestine amylase probably exerts its action even in artificially fed infants The significance of the rennin cannot at present be explained Morphological and cultural investigations showed that the bifidus form may be converted into the acidophilus form, and *vice versa* Since the ferments of both resemble one another, it is reasonable to suppose that these organisms are morphologically different forms of the same group which appears in nature as the ubiquitous lactic acid bacillus, and thus gains entrance to the infant's intestinal tract Since the enterococcus also forms lactic acid, it can likewise reach the intestine through the milk

476 Physiological Action of Insulin

THE effect of the intravenous injection of insulin in normal individuals is discussed by K ROHOLM (*Acta Med Scand.*, September 27th, 1930, p 472), who reports the results obtained in nine men and seven women from 17 to 63 years old The effect on the fasting gastric secretion was first examined The amount of gastric secretion, the peptic content, and the total acidity curves corresponded, in that they showed a slight preliminary rise and fall during the first twenty five to thirty minutes, there was then a marked rise to a maximum in about sixty minutes, followed by a gradual fall The amount of gastric juice increased, and there was a rise in the content of hydrochloric acid and of pepsin The blood sugar curve in fasting cases was found to drop for twenty five to thirty minutes after the injection and then begin to rise, more slowly The lowest blood sugar value coincided with the start of the gastric secretion The effect of insulin on the gastric secretion in hyperglycaemia or in normal blood sugar cases, obtained by giving the patient a 50 per cent glucose solution intravenously or through the stomach tube, was next investigated It was found that the blood sugar concentration determined the gastric secretion Hyperglycaemia completely inhibited gastric secretion, which, however, promptly began when hypoglycaemic values were reached Further, it was found that there was a threshold value of blood sugar concentration, 40 to 50 mg per cent, at which gastric secretion commenced A further fall in the blood sugar did not appear to affect the gastric secretion, nor did the rate of fall in the blood sugar concentration have any sure influence upon the gastric secretion Roholm remarks that the nature of the mechanism through which the gastric secretion is induced by hypoglycaemia is uncertain.

Who is your Patient?

A MAN or woman? Adult or child? A very necessary question when you prescribe *a remedy for constipation—unless it is* Agarol Brand Compound the original mineral oil and agar-agar emulsion with phenolphthalein. Then you need to give thought only to the dose And that is simple Begin with a tablespoonful for adults and a teaspoonful for children, at bedtime Reduce the dose as improvement takes place

No excess of mineral oil to make adjustments of the dose necessary An emulsion as fine as it can be made, that mixes thoroughly with the intestinal contents, carries unabsorbable moisture to them and makes evacuation easy and painless

Besides, it *gently stimulates* peristalsis, and thereby makes the result certain and the re-education of the bowel function possible

One tablespoonful at bedtime —is the adult dose

Final decision on the true worth of Agarol Brand Compound rests with the physician We will gladly send a liberal quantity with literature, for trial.

AGAROL BRAND COMPOUND *for Constipation*

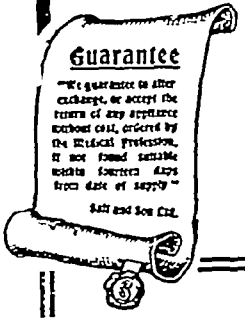
Modernity and Elastic Hosiery

In the present age, when strenuous exercise—especially dancing—is so prevalent, the danger of discarding elastic hosiery is obvious to Medical Men In order to prevent this risk we have produced our famous



"DRESS SILK" HOSIERY

which is inconspicuous when worn under the fashionable silk stockings of to-day

This is a special fabric made from finest China silk with rubber strands, and is naturally more expensive and not suitable for rough usage.

We supply, however, 10 qualities of Elastic Hosiery in eight different colours, to meet the requirements of all classes of patients

VICHY-CÉLESTINS

And the other State Springs of Vichy
(Property of the FRENCH STATE)

FERMENTATIVE DYSPEPSIA

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop Quite a series of acids are then to be met with (butyric, lactic, acetic, etc), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation **Vichy-Celestins,** by its slightly stimulating action, clears out the stomach, and this avoids stagnation and consequent fermentation As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition

CAUTION —Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

"ARDENTE" STETHOSCOPE

Mr R H Dent makes a Stethoscope specially for members of the medical profession suffering from deafness Many are in use and excellent results are reported on the latest as evidenced by the interest shown at the last B M A Meeting

1 It is individually fitted to suit the case for young middle aged or old
2. It is simple and true to tone and leaves the hands free
3. It removes strain thus relieving head noises giving inconspicuous hearing
4 It conveys sounds from varying ranges and angles.
5 It is entirely different uncopyable and carries a guarantee and service system
6 It is suitable for "hard of hearing" or acutely deaf through various causes
7 It is helpful for conversation, music, talkies wireless, home, office, public work and sports.

FREE HOME TESTS

arranged for Doctors and Patients

Medical Prescriptions made up to the minutest detail

MEDICAL REPORTS

Commended by all leading medical journals—Mr Dent will be happy to send full particulars and reprints on request

ASTHMA

There are certain types of chronic asthmatics who require relief of their paroxysms While adrenaline is generally effective it must be given hypodermically, and its action is short lived Vapo Cresolene (specially prepared cresols of coal tar) vaporized in the bedroom at night will give the desired relief The patient is not disturbed as he breathes the medicated air of the bedroom

This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough spasmodic croup

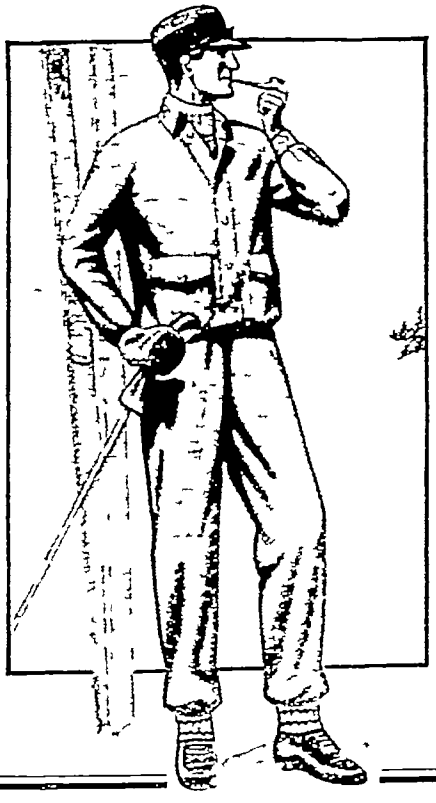
Rheumatic Cases Need Wool

The layman who wears woollen underwear knows that it is warm and comfortable, he is never conscious of the clammy feeling other underwear gives — wool is still comfortable after exercise

The facts are that medical evidence★ has proved that woollen underwear absorbs the damp of the body and holds it Even when there is a sudden change of temperature wool still holds the perspiration when other materials would let it condense back on to the skin.

Against chills—or rheumatism if it is dreaded—wool is specially useful, allowing free perspiration, protecting against sudden excesses of heat or cold

When you mention woollen underwear you are safe in recommending Wolsey It is pure, soft and comfortably shaped to individual needs



★
Details of the investigation made by the British Research Association for Wool will gladly be sent to any medical practitioner on application to Wolsey Limited, Leicester

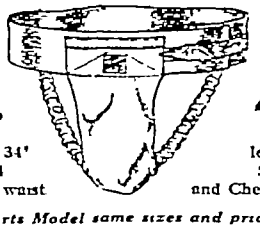
A definite advance



upon the old suspensory - bandage -

DOCTORS agree that the vital organs of man need adequate support and protection from strain as he reaches maturity especially in occupations and sports calling for unusual exertion. Hernia which, according to one authority claims one man in six would prove an avoidable trouble if men wore in time a protecting supporter

The "Litesome" Body Belt has already won notable approval from medical and surgical authorities, at least two going so far as to suggest that its regular use will not only be a defence against Hernia but render the wearer less liable to Varicocele and Prostate enlargement in later years

A Surgeon who has tested it writes
"It promotes a feeling of comfort, support, and increased virility which is inconceivable to the uninitiated."

THE 'LITESOME'
Body Belt & Supporter

STANIFORM
Regd. BRAND Trade Mark

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns scalds etc.

DUSTING POWDER
For application where a greasy substance is counter indicated

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis

LOTION
A panacea for Mosquito and other insect bites Most effective for all purposes where Tr Iodine is employed Does not stain the skin and there is no sting

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use

Supplies may be obtained through the Wholesale Druggists, Druggists Sundries men or Dental Supply Companies

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men

I have treated with Staniform a very bad scald of chest in a child who had boiling water spilt over her It healed completely in fourteen days without a scar

I have tried Staniform in the Out patients Department and both Nursing Staff and myself were amazed at results obtained Long standing non healing skin wounds healed after few applications

This is to certify that Staniform has been used with great success in the Emma Kliniek (Utrecht Holland) in cases of bed sores in burns of heat and X rays

Similar testimony has been received from a large number of medical men when Staniform has been used for the treatment of Burns Wounds and Skin Ailments

STANIFORM is used in Leading Hospitals

STANIFORM over a wide field of clinical experience has exhibited positive curative properties Combining the well known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine Staniform is indicated generally in local inflammations inducing an immediate soothing effect with rapid healing

President LORD WAKEFIELD OF HYTHE C B E LL.D
Treasurer SIR LIONEL FAUDEL-PHILLIPS Bart
Physician Supt J C LORTAN PHILLIPS M D, F R C P

This Registered Hospital is now situated at Monks Orchard in some 250 acres of park pleasure and farm grounds and is ready to receive patients Application can now be considered on behalf of patients of the educated classes in a presumably curable condition

With a view to early treatment voluntary or uncertified patients are admitted

Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise The Committee will also consider applications for admission at lower rates and in certain cases will be prepared to admit patients free of charge

Every facility for specialised investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit In this Unit is found the X ray and Dental Departments and the Bio Chemical Pathological and Psychological Laboratories

Furthermore provision is made for Electro Therapy and Hydro Therapy to be carried out in all their forms

In addition to the Resident Medical Staff Consultants in special branches of Medicine and Surgery are available whenever required

The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms

For forms and further particulars apply to the Physician Superintendent at the Hospital
